Two months ago we directed attention to the effort then being made to found an institution under the above title in or near Dublin, and we ventured to predict success for the charitable and humane gentlemen who had identified themselves with the project. We are now happy to be able to state that the wished-for success has, to a considerable extent, attended their efforts; that funds are being daily collected, or subscribed for, to a large amount; and that the idea bids fair to become a fact. To complete this, however, the friends of the undertaking should by no means relax their efforts; nor should they, who are disposed to give, withhold their money under the impression that more is not wanted. Very much more is wanted to place the institution on a permanent and sound basis.

In our former notice we referred to the exertions of

Dr. KIDD, the learned editor of our contemporary, the *Dublin Quarterly Journal*, and we directed the attention of our readers to his able pamphlet on the entire question. This pamphlet is, we understand, out of print; and as many are desirous of reading it, we hope the Committee will request Dr. KIDD to prepare a second edition, which will be the best possible advertisement of their charitable institution.

THE LUNACY ACTS (SCOTLAND) AMENDMENT BILL.

THIS Bill has undergone in the Committee of the House of Commons such alterations as fully justify us in accepting it as an amendment on the present law. These we shall point out more fully at an after period, at present we write to congratulate the profession on the prospect now held out to them of comparative immunity from risk in discharging their duty to lunatics, and to the public in regard to the dangers accruing to it from lunatics permitted to be at large. In our number for May 2nd, we printed the suggestions thrown out by the Royal College of Physicians of Edinburgh as to the improvement of this Act, and amongst them a clause proposed to be inserted for the protection of medical men, by which the two medical persons certifying as to the state of the supposed lunatic, were proposed to be appointed by the sheriff, and brought into action at his instance and request, thus constituting them for the time and case the servants of the court, and as such privileged defendants. We hold that considering the importance of the duty to be performed, and its influence upon the safety of the alleged lunatic and the public, it is hardly too much to demand complete immunity from persecution for its performance, and we think this clause was wisely constituted for that end, and we are sure that no one would grudge the sheriff his having the appointment of the "medical persons;" for the duty they are called on to perform is always difficult, not always free from danger, and one of the last which any sane man would voluntarily choose to perform for his friend. Still when we reflect upon the great jealousy with which the law very properly regards any interference with the liberty of the subject, perhaps it was really too much to expect that medical men, who in such cases have the liberty of the subject wholly in their own power, should be exempted from punishment for an even careless discharge of their most important duty, for wilful malversation we hope would never occur. And viewing the matter not only from the sensitive position we occupy as medical men, but also from the point of view of the general public, of which we are also members, we really think that the Legislature has hit the happy medium when it has proposed that medical men shall still be liable to be prosecuted for the supposed careless or negligent discharge of this as well as of every other duty, but has also proposed that all such trials shall come off not before a jury—compassionate to the suffering, untrained in the unravelling of motives, jealous of personal liberty, with minds at the mercy of their feelings, and these capable of being swayed like corn before the autumn wind by the *ad captandum* speech of any clever and not over scrupulous lawyer—but before a judge alone. In the scrupulous integrity of the Bench, the medical profession and the public together have a guarantee that such actions for damages shall neither be neglected if well founded, nor allowed to be unduly prolonged if frivolous and unjust. We beg again to con-

gratulate the profession on this decided amendment in our Lunacy Act, and to tell them that they owe it to the persistent perseverance of the Royal College of Physicians—perhaps too, quietly, to a small lesson the Lord Advocate got two years ago in regard to the Vaccination Act, and in a measure also probably to a not less important lesson, for him, which his constituency gave him last year.

Notes on Current Topics.

QUARANTINE AND THE CHOLERA.

SINCE the publication of our last number, the Government has taken some active steps with a view of checking the spread of cholera, but we regret to find that it still prevails in Liverpool, although not to a serious extent. The opinion that the disease has been brought from Holland by the German emigrants appears to be fully confirmed. At the time of our writing, nothing has been done in the port of London by way of precaution against the introduction of the disease, and although it has been stated that a hulk was to be moored near the *Dreadnought* for the reception of patients, that step has not yet been taken. It is satisfactory to know, however, that up to the present time no cases of cholera have been received on board the *Dreadnought*, or have come under the cognizance of the medical officers of that vessel.

DR. GEORGE JOHNSON'S THEORY OF CHOLERA AND ITS TREATMENT.

Verbum Sat.—Without entering at all into the merits of Dr. Johnson's pathological theory, which is ingenious and may be true, we at once demur to his practical corollary. In 1855 the Treatment Committee of the Medical Council addressed a report on the results of the different methods of treatment pursued in epidemic cholera to the President of the General Board of Health. From page 13 of this we quote the following:—

"The evidence of these (preceding) tables condemn the *eliminant treatment* altogether as a principle of practice.

"It testifies against the stimulant principle, except as a resource in extreme cases.

"It displays a decided advantage in the alterative principle, especially as carried out by calomel and opium; and it shows a still superior advantage in the astringent principle, as applied through the means of chalk and opium, the general percentage of deaths following each plan of treatment being:—

"Of eliminants	71.7 per cent.
stimulants	54 " "
alteratives, calomel and opium	36.2 " "
astringents, chalk and opium	20.3 " "

While at page 26 we find that in the treatment of simple and choleraic diarrhoea the largest percentage of failures to stay the disease in its earlier stages was attained by the treatment by salines, which reached 13.6 per cent.; that by eliminants generally reaching only 4.7 per cent.; by the treatment by opium in this stage, however, there was no failure to arrest the passage of the disease into cholera, though 2.6 per cent. died from diarrhoea alone; and at page 27 we read that the percentages of failure to stay the disease in its earlier stages, or in that of premonitory diarrhoea, shows "a decided preference to the astringent plan of treatment in the early stages of the disease, or in the premonitory diarrhoea." We have lived through three epidemics of cholera—1831-2, 1848-9, and 1854-5—

and now when we are about to have a fourth we think it of importance to reproduce these solid facts in opposition to the specious theory just promulgated. From a fair experience we can confidently recommend full doses of opium as an almost unailing specific against the premonitory diarrhœa, while we know of no cure for true cholera, save in careful nursing. Taken early, we can cure it certainly; let it run on and no cattle plague is more obstinate to treatment; but we hold it to be less absurd to hang onions round our cows' necks, and fancy we are curing them, than to treat our cholera patients by eliminants, in the face of these statistics, and hope to cure them.

ANIMAL QUINOIDINE IN RELATION TO DISEASE.

ANIMAL quinoidine is the term given to that peculiar substance allied to quinine in optical properties and chemical relations, which has been discovered by Dr. Bence Jones to exist in the flesh of animals (guinea pigs specially), as we pointed out in our last. At present we refer to it as the basis of a hasty, crude, and curious but captivating theory of disease, and the influence of remedies which has been propounded by Dr. Bence Jones, and in a measure adopted by Dr. Sieveking. Dr. Jones fancies that it is probable that the peculiar, unique, and specific action of quinine in ague is due to its artificially replacing a natural substance temporarily deficient or absent from the system from the action of malaria. Now at present we do not stop to inquire how, if animal quinoidine be indeed, as its discoverers suppose it to be, one of the earliest products of the retrograde metamorphosis of albumen, its mere absence can be so fraught with disaster, or its mere replacement so influential for good. While life holds on, albuminous substances must retrograde; if they do not do so normally, the anormal products of their metamorphosis must act as irritants somewhere in the organism, and so produce an anormal or diseased state of matters certainly not to be remedied *tuto, cito, et jucunde* by the mere supplementary addition, artificially, of a proper amount of their normal products; that is a matter by itself, lying indeed on the very threshold of the inquiry as to what is disease, but not concerning us at present. To view the matter profitably from this point of view, we must first be prepared to prove that animal quinoidine is really the product of the retrograde metamorphosis of albumen, which has not yet been done, and which we are most certainly not prepared to do. What we propose to do now is not to inquire into the truth of this theory, but simply to inquire of our friends, the chemists, who have so kindly proposed to solve our mysteries, if they are prepared to accept the consequences of this theory, for if so the transmutation of metals lies not far ahead, the philosopher's stone shall soon be discovered, and even the obtaining the *elixir vitæ* need not be regarded as an impossible achievement. We know not how far chemists are justified in our present state of knowledge in accepting certain peculiar coloured lines in the spectrum as indications of the existence in the sun, moon, and stars, of chemical substances identical with those we have here. This must be determined by the amount of faith to be reposed in the means of investigation employed, and what that is we know not; but we can see that pushed to its legitimate extreme in its present direction it leads to a curious result. For if the appearance of extra violet rays or any other kind of rays

in the spectrum justify us in conclusively assuming the presence of quinine or quinoidine, and if the deficiency or absence of this quinine be the cause of ague, the cure of which is due to the artificial replacement of this natural product, removed from the system by the morbid agent. If this be legitimate reasoning, and such the true theory of the action of quinine, then whatever cures ague must act in a similar manner in replacing this defective product. It is possible that all febrifuges, such as bitter tonics, stimulants, opium, and particularly arsenic, can be readily believed by chemists to contain the elements of quinine or quinoidine, and to act, as they must, if this theory holds water at all, by restoring to the body this lost product; but if so we envy them their faith, which seems based, like that of Tertullian of old, on impossibility—"Credo, quia impossibile est"—and we confidently look forward to a new era in chemistry, which will more completely upset all our present ideas than would the actual extraction of sunbeams from cucumbers or food from fæces; and we ask can this faith in the chemical identity of quinine, opium, and arsenic, include also that of cobwebs and the exhalations of spiders—for we know it was not necessary to swallow spiders to cure a fever, but only to hang it "round the neck in a nutshell?" Be that as it may, however, we can state for our part that, before going farther in this direction, it would be most desirable to ascertain the influence of these arancous exhalations on the spectrum.

THE CASE OF DR. ARMSTRONG OF GRAVESEND.

THE late trial in London, which resulted in a verdict for Dr. Armstrong, presents some points of interest in reference to the conduct of the medical witnesses for the plaintiff. These witnesses were Mr. Francis Bonney and Mr. Vinall, and although some rather severe remarks have been made upon the part taken by these gentlemen, we believe that one of them at least—namely, Mr. Vinall—is hardly deserving of blame, and something may be said in favour even of Mr. Bonney. The evidence of both amounted, in fact, only to this—namely, that the symptoms under which the plaintiff suffered *might* be due to salivation, but neither, so far as we are aware, deposed that Dr. Armstrong or his son had salivated her. Mr. Vinall was, it is admitted, an unwilling witness, and when it was proposed to him, some time before the trial, to pay him for his attendance out of the expected proceeds of the lawsuit against Dr. Armstrong, he unhesitatingly declined to attend any longer. He was subpoenaed only the day before the trial. Mr. Bonney's conduct in the affair was not, perhaps, altogether so satisfactory, but he declares that he attended the trial only because he was subpoenaed, and that he was in no way concerned in getting up the action. Those who know how these matters are managed should be informed that a medical witness who receives a subpoena is sometimes quite ignorant of the questions which will be put to him, and the counsel is always ingenious enough to frame his questions in such a way as to elicit precisely the answers which will serve his purpose. Mr. Vinall, as having actually attended the case, was compelled to appear and give evidence, and was not in the position of a person who merely offers scientific opinions, and who is not obliged to appear at all. It was not quite so clear that Mr. Bonney had nothing to do with the preliminary proceedings, and we sincerely hope

that he had not; but in a disclaimer which he has published he states most positively that he offered no opinion upon the case, and that what he did state was only in answer to questions put to him by the counsel. A subscription has been on foot to reimburse Dr. Armstrong for the expenses to which he has been put, and we have no doubt that the Profession will readily come forward in answer to the appeal.

THE PROGRESS OF CHOLERA.

THE course of this mysterious disease still continues to baffle the investigations of science, as its treatment has hitherto defied the powers of medicine. In one case we find the malady breaking out in a ship at sea, six days after leaving harbour, and sweeping off more than a hundred victims before the vessel crossed the Atlantic, and then we hear of another ship putting into an Irish port in consequence of the cholera having appeared on board, but being refused admittance into Ireland, and then bringing the disease into Liverpool. Fortunately, however, notwithstanding the manifest danger to which the people of Liverpool were thus exposed, the disease has not spread to any considerable extent, and, indeed, we might say (at the time we are writing) that it has not spread in Liverpool at all, the deaths having occurred entirely among the emigrants. But we regret to add that Dr. Ross, the assistant-surgeon on board the *Helvetia*, who had attended with great assiduity the patients in that ship, was attacked with the disease and died in a few hours. As far as the mortality is concerned, it seems fair to conclude, if we may judge from what occurred on board the *England*, that the disease has been checked on board the *Helvetia*, and the cholera poison dissipated by the precautionary measures adopted; but so contradictory and apparently paradoxical are many of the facts developed in reference to cholera, that it would be presumptuous even yet, with all our experience of its visitations, to commit ourselves to any dogmatic opinions on the subject.

THE ARMY AND NAVY MEDICAL SERVICES.

IF our brethren of the Army and Navy Medical Services are disappointed at the non-adoption of the recommendations of the Committee appointed to consider the questions so long in agitation in reference to their rank, pay, and retirement, the fault is certainly not ours. In publishing some of the principal recommendations, we distinctly stated that they had not been adopted by the authorities at the Horse Guards, and we subsequently intimated our opinion that they would not be adopted in the case of the Army, although there was every disposition to carry them out by the Admiralty. What we then stated (now more than two months ago) turns out to be strictly correct, and we are now informed that the Commander-in-Chief has recommended the War Office to pay no attention, at least for the present, to the recommendations of the Committee, and although the Admiralty is disposed to favour the Medical Officers of the Navy, yet the Government declines to sanction the supplemental estimate for the Navy, in consequence of the course pursued by the authorities of the Army. We very much regret the course which has been taken by the Commander-in-Chief, and we could have wished that our opinions had been falsified, instead of being confirmed by the event.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION, 1866.

[FROM OUR SPECIAL REPORTER.]

ON Thursday last, at two o'clock p.m., the Medical Council of Great Britain commenced its sittings at the Royal College of Physicians of London, under the Presidency of Dr. BURROWS. The members having, with one exception (Dr. Christison), answered to their names, the business of the meeting commenced with an Inaugural Address from the President, in which he reviewed briefly the proceedings of the last General Council, alluded to what was then proposed and carried, and what was left uncompleted, and the steps which he trusted would now be taken into the serious consideration of the Council. Many, he said, desired that the Council should meet oftener, as topics which were of the greatest importance to the profession at the time they suggested themselves, faded away from memory amidst the business and anxiety of life, leaving no trace of their ever having been properly discussed in the deliberations of the Medical Council of the United Kingdom. There were several matters now before them so important and pressing as not to suffer delay, and those who valued the powers given by the Act of Parliament should not allow them to remain dormant, but by immediate and united action, should immediately endeavour to obtain the earnestly desired ends. He said with respect to the visitations of the various bodies on examinations, that they would, in his opinion, be of no avail, unless conducted thoroughly and impartially in all its branches. Having, *en passant*, alluded briefly to the compilation of the British Pharmacopœia, its utility and expense, he (the President) said he had that day received a communication from the Secretary of State, Sir George Grey, in reply to repeated applications from him, besides one personal interview with which he was favoured, relative to "The Medical Bills." The Executive Committee of the Council had endeavoured, as far as possible, to carry out, in connexion with her Majesty's Government, the designs and purposes of these Bills. In the last Session of Parliament they were told, and not without reason, that there were so many bills to be considered, and so much work to be done, that the Council in these matters could not possibly obtain the consideration they were entitled to, and so the opportunity passed away. Since then we had lost our Premier (Lord Palmerston), and now a new Parliament was assembled. In February of this year the Government was very much engaged with two or three exciting questions, as the cattle plague, the Fenian conspiracy, and the Jamaica rebellion; but now he hoped something would be done to rectify the evils in the "Medical Acts," and with their permission he would lay on the table the despatch he had that day received from Sir George Grey.

Committees were then appointed for

The Business of the Council;

Finance; and

For the Amendment of the Medical Acts.

Most of the members of the last Committees again consented to serve during the present Session.

COMMUNICATION FROM THE HOME SECRETARY RESPECTING THE MEDICAL ACTS.

Before the first resolution on the programme was read, a Member suggested that the Council should immediately have read to them the despatch from the Secretary of State, as they would then be in full possession of the feelings of the Government regarding the Medical Acts.

The PRESIDENT thought it should not go forth to the profession and the public at large until it had been considered by the Council; and that if it were then read, he moved the reporters should leave the room.

This caused a very animated discussion as to the propriety of such a course, Sir Dominic J. Corrigan and several other members strongly opposing the expulsion as suggested, considering it sufficient to throw out a hint that it was not desirable the document should at present be reported.

Dr. ACLAND proposed, that the reporters should in no way be bound, but that as they were admitted on public grounds, it should be left to their discretion to report or to suppress what they pleased. This view was eventually adopted.

The letter was then read, and appeared to cause not a little amusement to the Council.

It was proposed and seconded, that the letter, with the accompanying document, be printed and circulated amongst the members of the Council. Motion carried.

GRANT FOR INVESTIGATING THE ACTION OF MEDICINES.

Moved by Dr. ACLAND, and seconded by Dr. STOKES:—
 "That the memorial from the Physiological Section of the British Association be received and entered on the minutes. That, in conformity with the suggestions of the memorialists, the sum of £250 be placed in the hands of a Committee to be hereafter nominated. That it be an instruction to the Committee to expend the whole or part of that sum in obtaining investigations or reports calculated to promote a precise knowledge of the efficiency of remedial agents, either of those heretofore esteemed to be of service, or of substances which the progress of science may point out as likely to be of value in the prevention or the treatment of disease."

MEMORIAL.

"BRITISH ASSOCIATION, BIRMINGHAM, 1865.

"Having regard to the observations of the President (Professor Acland), in his inaugural address, the Committee of the Sub-section of Physiology desire respectfully to intimate their opinion of the great advantage which would accrue to physiological (and thereby to medical) science if the General Council of Medical Education and Registration should think fit, by pecuniary grants, and the appointment of suitable persons to undertake investigations into the physiological action of medicines.

"A few agents when administered in poisonous doses have alone been made the subjects of such research; and whilst the remedial effects of even such well-known agents as quinine have been admitted for ages, their modes of action are still unknown. Even to this moment our knowledge of the action of remedies rest only upon ordinary observation and general inferences.

"The Committee is well aware of the extreme difficulty of prosecuting exact inquiries in states of disease, and, above all, of the necessity for devising new modes of investigation; but bearing in mind recent researches of an analogous nature in health, they do not doubt there are physiologists and physicians of proved ability in such researches who would be able to devise the methods and bring the results to a satisfactory conclusion.

"The Committee also venture to suggest that no experiments should be regarded as satisfactory which, in addition to others, are not made on ordinary medicinal doses in the diseases for the relief of which the remedies are administered (as well as in poisonous doses), and which are not performed with all the care and exactitude known in modern physiological research.

"That this resolution be signed by the President, Vice-President, and Secretaries, on the part of the Committee and that the President be requested to present it to the Medical Council of General Education and Registration."

Dr. ACLAND, in a very able speech, advocated the measures proposed as very conducive to the advancement of science in general, enumerating the many expenses incurred by the meetings of the Council—namely, £1700 upon the meetings of 1865, and from £5000 to £6000 on the Pharmacopœia; the latter he considered made more perfect by

a small grant—say £250—for the prosecution of scientific experiments, that such investigations might not be left, as they often were, to the energy of private individuals. He concluded by asking the Council dispassionately to consider the memorial in its various bearings.

Dr. ANDREW WOOD argued strongly against the grant of any sum for such purposes, and doubted, even if they were so disposed, whether they could legally do so, the Act distinctly specifying that no grant could be applied for such purposes; and if it was merely for the advancement of science, then the Council, who were not a scientific body, had nothing whatever to do with it. He (Dr. Andrew Wood) suggested that the British Association or some other scientific body—if they were so anxious for these experiments—should draw upon their own purse-strings for the expense of conducting them, and not throw the responsibility on the Medical Council, who had no interests to further in the matter.

Mr. COOPER considered Dr. Acland's requisition a most modest one, and maintained that the subject had not been lost sight of by external bodies; he would heartily support the memorial.

Sir D. J. Corrigan, Dr. Stokes, Dr. Alexander Wood, Dr. Sharpey, Dr. Quain, Dr. Smith, Dr. Apjohn, and Mr. Hargrave, having commented on the different points in the memorial,

Dr. ACLAND rose to reply, thanked the Council for the consideration they had given the subject, and proceeded in a somewhat lengthy *résumé* to meet the many objections raised against his motion.

The amendment of Sir D. J. CORRIGAN—

"That the proposed investigation does not come within the province of the General Medical Council; nor, were it within their power, have they any legal authority to expend their funds on such an inquiry," having been put to the vote and carried, the motion of Dr. ACLAND was consequently lost.

ADJOURNMENT ON SATURDAY.

The next motion on the programme was then put by Dr. ALEX. WOOD:—

"That when the sittings of the Council shall extend over a Saturday, the Council shall on that day assemble at ten a.m., and adjourn at one p.m."

This was seconded by Sir D. J. CORRIGAN.

Amendment proposed by Mr. HAWKINS:—

"That the Council should on that day sit from one to four p.m."

The PRESIDENT spoke strongly of the inconvenience which would arise if Dr. Wood's motion was carried, considering the measure most unbusiness-like, and framed for the convenience of one or two country members; he would oppose the motion, but would not object to the compromise proposed in Mr. Hawkins's amendment.

The motion was then negatived, and the amendment carried by a large majority.

REPORT OF BRANCH COUNCILS.

A long discussion followed on the mode of presenting the various reports from the Branch Councils, in which the majority of the members took part.

Dr. ALEXANDER WOOD then proposed, and Mr. HARGRAVE seconded—

"That the Reports from the Branch Councils, and from the members of these Branch Councils deputed by them for examination, be printed and circulated, and that the Business Committee be instructed to set apart an early day for their consideration." Carried.

FRIDAY, MAY 18TH.

The Council resumed their sittings at the usual hour, with the consideration of the Report of the Committee on General Education, deferred from last session.

Dr. STOKES moved that the Report be now considered.

Mr. RUMSEY maintained that the short time allowed for the discussion of the many subjects during a single session of the Council was insufficient to give due consideration to so important a question as that proposed by Dr. Stokes. He suggested that it be referred to a Committee during the interval of the session, as more time and attention could then be given it.

Dr. ANDREW WOOD, who proposed an amendment, and also Dr. ALEXANDER WOOD, severely censured the idea of again delaying this important measure, which had been postponed from year to year, merely because the Council did not care for it or dared not face it, and he maintained that the time had now arrived, after the lapse of so many years, when the old machinery of medical education should be revised, and that, as so many of its bearings had now become obsolete, the whole matter should be immediately taken up and thoroughly and practically tested.

Dr. STOKES having consented to withdraw his motion,

Sir DOMINIC CORRIGAN moved an amendment to the effect that in the preliminary examination, students should be required to have a knowledge of Greek. He considered this minimum standard would not be too restrictive in its operation, as unless every young man who comes up for examination (with a view to being admitted into their learned profession) had some knowledge of this most desirable of the classics, he should not on any account be allowed to practise as a duly qualified medical man. He instanced the case of a student under his own notice, who, when asked the definition of physiology, replied, after some hesitation:—"Sir, I believe it is a fungus." Sir Dominic resumed his seat amidst loud laughter.

Dr. PAGET said the amendment proposed by Sir D. J. Corrigan was very desirable, and he, for one, hoped the time was not far distant when a knowledge of Greek would be made compulsory, yet in the present unsatisfactory state of medical education he did not think the Council could possibly insist upon this clause. There was still a very lamentable ignorance of Latin, and if the study of this language was more strictly enforced, they would not hear so many complaints from the Army and Navy Departments, and from the Examining bodies generally, of the incapacity and the positive ignorance of so many of the candidates.

Dr. ARJOHN hoped the clause would be embodied in the original motion, a knowledge of Greek being in his opinion most essential.

Dr. STORRAR held Greek to be desirable, but such a thoroughly disciplined education in Latin, or even in English only, as would fit a man for his position and for the proper performance of his duties, was by far the most important of the many subjects before them for the advancement of medical education.

It having been suggested that the amendment, or the insertion of the clause in Dr. Wood's motion, be for the present withdrawn,

The amendment of Dr. ANDREW WOOD, seconded by Dr. PARKES,

"That the Report of the Council of General Education be referred to a Committee,"

was then put and carried, Monday being named for its consideration.

RETURNS FROM THE ARMY AND NAVY SERVICES.

The second and third items on the programme were then proceeded with, and communications were read from the Director-General of the Army Medical Department relative to returns of the Examinations of Candidates for Medical Commissions in the Army, and from the Director-General of the Medical Department of the Navy, with returns of the Examinations of Candidates.

A communication was also read from the Under-Secretary of State for War on the Entry of Medical Qualifications in the "Army List."

MEMORIAL OF THE IRISH MEDICAL ASSOCIATION ON MEDICAL EDUCATION.

A letter from Dr. Mackesy, President of the Irish Medical Association, relative to Defects in Medical Education, was then read, in which reference was made to another letter relative to the same subject, having been addressed by Sir Dominic Corrigan to Dr. Mackesy. This communication led to a very animated debate.

It was proposed and seconded that Dr. Mackesy's letter be entered on the minutes.

Amendment proposed by Dr. PARKES, seconded by Mr. SYME,

"That the Council do now pass to the order of the day."

This was negatived.

Dr. ACLAND proposed, as an amendment, that the words "be entered on the minutes" in the original motion be left out, and in lieu thereof be inserted, "Be referred to the Council on General Education."

This amendment was carried by 15 to 8.

In reply to some rather severe strictures on the part of Dr. Alexander Wood, in reference to the conduct of Sir DOMINIC CORRIGAN in furnishing materials for attacks on the Council,

Sir DOMINIC said—Although I have already spoken, I claim a right to reply to what I must designate as a personal attack on me by the President and Dr. Alex. Wood, the representative of the Edinburgh College of Physicians. You, Sir (to the President), have charged me with making erroneous statements ("No," from the President). Your words, Mr. President, were, that I committed "errors in my statements" in the extract from my letter to Dr. Mackesy. I meet you on that phrase "errors in statement," and you have on that ground objected to the publication on our minutes of Dr. Mackesy's letter. Dr. Wood's language has been unmeasured. He has dared—I would not use the phrase "dared" but that he has presumed to use it in addressing me—to say that in my letter to Dr. Mackesy I have given utterance to opinions in reference to Medical Legislation and the action of the General Medical Council, for which I am bound to make an apology—a most humble apology to the Council—in presuming to say that there is a competition among the several licensing bodies for the sale of diplomas, and for saying that I am hopeless as to any amendments while such competition is permitted to continue. My reply to the President's charge of errors in statement, and to Dr. Wood's demand of apology is this, that I stand by every syllable, every word of that communication, every fact and opinion I have expressed in it. I have over and over again stated here the facts and opinions I have expressed in that letter, and I shall now state them once again in stronger language, and prove, I hope, that I have not committed any errors in statement.

The President interrupted Sir D. Corrigan, and said that he could not permit him to continue, as he (the President) had not referred to the extract of a letter in Dr. Mackesy's communication as coming from Sir D. Corrigan, but, as stated by Dr. Mackesy, to have been written to him by an influential member of Council without mentioning his name.

Sir D. Corrigan continued—I will not submit to be silenced thus even by the Chair. You did not, Sir, comment on the extract as that of an anonymous correspondent. As soon as the letter was read I at once stated that I was the writer of the extract referred to, and with that knowledge you proceeded to enter into the discussion of it, and to charge me with "errors in statement." What I state in that extract is, first, that the General Medical Council had no power to enforce rules or regulations as to preliminary or professional study, and I instanced the case of the Edinburgh University,

which refused to recognize the resolution of the General Medical Council as to its degrees, as an early instance of this Council having no power. This Council, we all recollect, was obliged to succumb, and the Edinburgh University pursued its own course. Notwithstanding this fact before us, the President tells me I committed an "error in statement." Let me give another proof that I was right in saying this Council has no power to enforce rules as to education. It acknowledges itself by its own acts that it has no power. If it had the power to enforce rules as to education, then it has been lamentably deficient in not having done so long before this. I have not, then, made an "error in statement" in saying that the General Medical Council has no power to enforce its rules. The second "error in statement" charged against me by the President is, that I have said "the various licensing bodies may do as they like." Is it not notorious that they are doing as they like at the present time in the eighth year of our existence. There is not at present a single licensing body in the empire, except by accident, coinciding in their action with the recommendations of the General Medical Council. On the several points of preliminary examination, on professional study, on the date of commencement of professional study, or on its duration, all the licensing bodies do as they like, and some of them are even authorized, and even necessitated by Acts of Parliament or Charters, not to depart from their previous usages, not to comply with the recommendations or rules of this Council. I need not adduce instances. Every member of this Council is aware of the truth of what I say (hear). The third point which has been found fault with by Dr. Wood is the expression of my opinion, that I have no hope of amendment in medical legislation or from the Council while the present lamentable competition among the several licensing bodies for the sale of diplomas is permitted to continue, and it is for the expression of this opinion that Dr. Alex. Wood has presumed to say I have offended the Council, and that, in his opinion, I owe a deep apology to the Council for imputing to licensing bodies and their representatives on the Council the supposition of their being actuated by sordid pecuniary motives. From whom has this attack upon me, conveyed in language such as should not have been used, come? From the representative of a licensing body that acted in such a way as to render it utterly impossible to suppose its being actuated by any but sordid pecuniary motives, impossible to conceive it as having the slightest regard for the honour or education of the profession—a body that sunk itself to the lowest depth of dishonour in selling its diplomas—a depth to which I am glad to be able to say no other of our licensing bodies has descended. Let me recall to the recollection of this Council what the College of Physicians of Edinburgh did soon after the passing of the Medical Act of 1858. Dr. Wood, President, and the College of Physicians of Edinburgh, knew there were hundreds of practitioners in the United Kingdom who desired in the coming registry to have a licence to practise medicine annexed to their names who had no medical qualification, and had never undergone an examination in medicine. The College of Physicians of Edinburgh issued an advertisement that they would give their licence and supply the required qualification in medicine for ten guineas a head without any examination to all persons who could show any title to have their names on the registry, whether as merely surgeons, apothecaries, or licentiates in midwifery; and this College thus sold this false diploma certifying that the possessor was competent to practise medicine, although they never examined him. It is said £10,000 were made by this sale of diplomas; and now the representative of the body that did its discreditable act, a party to it, presumes to say that the honour of his College is impeached, that his fine feelings are hurt, and to call me to account for saying I have no hope of

amendment while licensing bodies are permitted to compete for gain in the sale of diplomas. Dr. Wood cannot forget—I am sure every member of the Council may recollect—even the debate on the subject of that discreditable occurrence when I proposed that licences given without examination—meaning those of the Edinburgh College of Physicians—should not be registered, and announced my intention of following up that resolution, if passed, by bringing the conduct of the College of Edinburgh before the Privy Council; that Dr. Wood only saved the College from further exposure by an appeal *ad misericordiam*, and a promise that they would not sin again. I said I would express my opinion as to the competition permitted under the present state of legislation in stronger terms than I used in that letter. I do it now in the same terms I have used on more than one occasion in this Council, that the present competition among the several licensing bodies is "a battle of shops" for the sale of diplomas. Let us look to the Army and Navy returns of those passed and those rejected. More than one-half of those rejected, or about that proportion (I only quote from memory), are declared by the Examiners to have been rejected as utterly ignorant of Latin and of orthography, or the simplest rules of English composition, and the same ignorance is found as to anatomy, surgery, and therapeutics. These ignorant persons, rejected as unfit for army and navy, are let loose upon the public, and from what cause, from competition among licensing bodies in the sale of diplomas. Dr. Mackesy, in his letter to this Council, and in the extract from mine which he has inserted in it, has hit the blot, and hence you shrink from publishing his letter.

SATURDAY, MAY 19TH.

PETITIONS FOR REGISTRATION.

The business of the day commenced with the consideration of an application from Mr. William Adams, formerly of St. Ives, to be restored to the Register. From a statement made by the Registrar of the Council, an erroneous impression had gone forth through the obituary of the *Lancet* that this gentleman was dead, consequently his name was omitted from the Register. The letter of Mr. Adams having been read, his name was ordered to be again inserted on the Register. A petition from Mr. Richard Organ, to be again allowed to offer himself for examination with a view to being placed on the Register. His name had been formerly erased, as the Council then sitting decided his diploma had been fraudulently obtained.

Dr. ALEXANDER WOOD moved, seconded by Dr. SMITH, "That the application of Mr. Richard Organ, having been reconsidered, be rejected."

Application dismissed without a dissentient voice.

A letter was also read from Dr. Steele, Registrar of the Branch Council for Ireland, with an application from a student to be registered.

After a long discussion, in which Dr. Andrew Wood, Sir Dominic Corrigan, Mr. Hargrave, Professor Syme, Mr. C. Hawkins, Dr. Alexander Wood, and Dr. Storrar took part, the matter was referred, to give precedence to the motion of Dr. Smith seconded by Dr. Storrar,

"That a Committee be appointed to consider and report upon the working of the system of Registration of Medical Students adopted by the General Council last year."

A Committee was then appointed (Dr. Embleton as Chairman) to take the matter into consideration.

(On the resumption of the matter of Dr. Steele's letter, accompanying an application from a Student,

It was proposed by Dr. Storrar, seconded by Sir Dominic Corrigan, "That this letter be referred to the Committee just appointed, ten o'clock on Monday being named for its meeting.

STANDING ORDERS.

After a few preliminary remarks, a notice of motion was

brought forward by Dr. Fleming for the appointment of a Business Committee to move some additions to the Standing Orders and Regulations.

Dr. ALEXANDER WOOD did not deem it necessary to appoint the Business Committee proposed by Dr. Fleming, and begged of Dr. Fleming to withdraw his resolution.

Mr. SYME coincided in Dr. Alexander Wood's view.

Dr. FLEMING withdrew his motion.

Sir D. CORRIGAN drew attention to the resolution of April 15, 1865, of the General Medical Council, directing that a proof copy of the Pharmacopœia should be placed in the hands of each member "at least one month before the meeting of the General Medical Council, at which the opinion of the Medical Council is to be given relative to its being published, &c." Sir D. Corrigan observed that the resolution referred to had not been complied with; but as the omission had occurred, he desired to know if proof copies would be supplied with the view of obtaining suggestions.

The PRESIDENT and Dr. QUAIN, members of the Pharmacopœia Committee, gave an assurance that proofs should be in the hands of members as desired.

Dr. STOKES, Chairman, laid on the table a report from Education Committee.

The Council then adjourned.

Parliamentary Intelligence.

HOUSE OF LORDS.—MAY 14TH.

CONTAGIOUS DISEASES BILL.

THIS Bill passed through committee.

HOUSE OF COMMONS.—MAY 11TH.

THE MORTALITY AMONG THE TROOPS AT HONG-KONG.

Mr. LOCKE asked the Secretary of State for War whether the 20th Regiment (2nd battalion) had been ordered, or whether it was the intention of the Government to order it from Japan, where it is at present stationed, to Hong-Kong, to occupy the quarters vacated by Her Majesty's 11th Regiment, in which such mortality had lately occurred, or whether it was the intention of Her Majesty's Government to send native troops to that station.

The Marquis of HARTINGTON said that the 2nd battalion had been ordered from Japan to Hong-Kong, but would not necessarily occupy the quarters vacated by the 11th Regiment.

Colonel NORTH asked whether the 2nd battalion of the 20th was to go to Hong-Kong upon the understanding that General Guy was to have unlimited authority to incur expense to provide quarters for them; and also whether he had authority to employ native watchmen in order that the European soldiers should have six or seven nights' continuous freedom from night duty.

The Marquis of HARTINGTON replied that orders had been given to diminish night duty by the employment of native watchmen, so that the soldiers might have six or seven nights' continuous rest. Orders had not been issued that General Guy might incur unlimited expense, but there was no reason to suppose that there would be any difficulty in finding accommodation for the troops.

In the Committee of Supply the following sums were voted:—

£1183, for allowances granted to the public infirmaries in Ireland.

£3845, for certain hospitals in Dublin under the central board of superintendence.

MAY 15TH.

CATTLE PLAGUE IN IRELAND.

In answer to questions from Mr. Gregory, Lord Naas, and other Irish members, Mr. C. FORTESCUE said there was too much reason to believe that the cattle plague had made its appearance near Belfast, and explained the stringent measures which had been taken to stamp it out.

THE CHOLERA.

Mr. SANDFORD asked what precautionary measures had been taken by the Government against the spread of cholera.

Mr. H. A. BRUCE replied that the powers possessed by the Privy Council were given by the Quarantine Act of George IV., and under it they had directed local authorities at the outports to visit all ships arriving from suspected quarters to prohibit the landing of infected persons, and, if necessary, to take measures to isolate them, and they had also offered to place any town which desired it under the provisions of the Diseases Prevention Act. This country he pointed out, had never acted on the system of quarantine; we had always depended on the local authorities, and our best security must be in improved sanitary regulations, such as better supplies of water and increased ventilation and cleanliness.

UNIVERSITY OF LONDON.

A MEETING of this University was held on the 9th, at Burlington House, Piccadilly, for admitting to degrees those students who had entitled themselves to these distinctions; George Grote, Esq., Vice-Chancellor (in the absence of Earl Granville, Chancellor), presiding. The members of the senate present were, in addition to the Vice-President, Dr. Billing, Mr. James Heywood, Dr. Sibson, Dr. Sharpe, Dr. Wood, Professor W. A. Miller, Dr. Gull, and Dr. Storrar. Among the visitors were the Bishop of St. David's, the Bishop of Derry, the Haytian Minister, Lord Belper, Sir J. F. Burgoyne, Mr. Scholefield, M.P., Mr. T. Dyke Acland, M.P., and Mr. Whalley, M.P.

The Vice-Chancellor, on assuming the chair, touched on the cause of Earl Granville's absence, which was the late serious and afflicting family bereavement with which the public are already acquainted.

The Registrar then proceeded to read a report showing the number of students who had matriculated during the past academical year—viz., 255 (50 being with honours) in June, and 120 (23 being with honours) in January.

The following is a list of the respective degrees and the names of recipients:—

M.D.—F. Buszard, W. Dale, T. Fairbank, S. J. Gee, F. W. Gibson (worthy of medal), G. H. Harries, C. A. Hingston, E. Holland, H. Jeaffreson, H. L. Kempthorne, T. Morton, W. Rickards, E. Smith, R. P. B. Taaffe, T. J. Woodhouse.

The graduates who had simply passed the examinations for the other degrees were next presented in the order in which their colleges are ranked in the calendar of the University.

M.B.—G. W. Grabham, D. M. Maclure, T. R. Glynn, W. A. Harvey, F. W. Richards, F. F. Lee.

Those graduates who have passed with honours were next presented one by one, and received their certificates from the Vice-Chancellor:—

M.B.—R. C. Powles, G. Oliver, B. H. Allen, C. A. Greaves, G. H. Savage, W. V. Snow, R. D. Powell, H. Trimen, T. H. Green, E. F. Turner, A. G. Mickley, F. T. Tayler, T. Bond, C. Smith, P. M. Deas, W. G. V. Lush, A. Bruce.

M.S.—P. M. Deas, E. Andrew.

The graduates to whom a scholarship, medal, or prize had been awarded, were next presented for the distinctions they had gained:—

M.D.—H. L. Kempthorne, medal.

M.B.—R. C. Powles, scholarship and medal in medicine; G. Oliver, medal in medicine; R. C. Powles, scholarship and medal in midwifery; A. G. Mickley, medal in midwifery; P. M. Deas, medal in forensic medicine.

M.S.—P. M. Deas, scholarship and medal in surgery; E. Andrew, medal in surgery.

First M.B. Examination.—J. McCarthy, exhibition and medal in anatomy; H. F. Parsons, exhibition and medal in physiology, histology, and comparative anatomy; W. A. Richards, exhibition and medal in organic chemistry, and materia medica and pharmaceutical chemistry.

Preliminary Scientific M.B. Examination.—T. Anderson, exhibition in chemistry and natural philosophy; W. A. Brailey, exhibition in biology.

The Vice-Chancellor, on the completion of the presentations, addressed the meeting, again regretting the absence of Earl Granville. He rejoiced at the liberal spirit which the Government seemed disposed to evince towards the university. The Government had declared their intention at last to provide the University with an adequate and substantial building of their own, and a sum of £20,000 had been asked for by Mr. Cowper on account of the first expenses of the building which would cost in the aggregate £65,000. He rejoiced also that it was stated in the speech of Mr. Gladstone, in introducing the Reform Bill, that it was intended to erect the University of London into a parliamentary constituency, which was to return one member. These two important measures indicated that the University was approaching its period of maturity, after a somewhat inconvenient prolonged minority (hear, hear, and laughter). The proposed building was one of the most pressing wants of the University, and he fully approved of the site. The Vice-Chancellor, in the course of an eloquent speech, addressed words of encouragement to the unsuccessful competitors, and concluded by advising the successful candidates for honours not to be elated by their present success, because that very success had raised additional expectations of future achievements (cheers).

The proceedings then terminated.

MEDICAL ACTS AMENDMENT BILL.

DRAFT OF A BILL

TO AMEND THE ACTS RELATING TO PRACTITIONERS IN MEDICINE AND SURGERY.

ARRANGEMENT OF CLAUSES.

SECTS.

1. Construction and Short Titles.
2. Amendment of Sect. 7 of Act of 1858.
3. Erasure by Order of Council.
4. Restoration of Name.
5. Repeal of Sect. 14 of Act of 1858.
6. Registers to be corrected.
7. Erasure on Death.
8. Alteration of Address, &c.
9. Evidence of Death, &c.
10. Erasure on ceasing to practise.
11. Registration of Foreign and Colonial Practitioners.
12. Privy Council may add to List of Qualifications.
13. Application of Provisions 20, 21, 22, of the Medical Act, 1858.
14. Degree of Bachelor of Surgery to be a Qualification.
15. Repeal of Sect. 40 of Act of 1858.
16. Penalty for Use of Title of Doctor, &c., by unregistered Persons.
17. Extension of Savings in former Acts.

BE it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

PRELIMINARY.

1. The Acts described in the Schedule to this Act and this Act shall be construed together as One Act; and for that purpose the expression "this Act," when used in the Medical Act (of the Session of 1858), shall include the present Act; and the Acts described in the Schedule to this Act and this Act may be cited together as "the Medical Acts," and are comprised in that expression when hereafter used in this Act; and this Act may be cited separately as the Medical Acts Amendment Act, 1865.

MEMBERS OF COUNCIL.

2. Section seven of the Medical Act (1858) shall be read and have effect as if the words "qualified to be" were omitted therefrom.

REGISTRATION.

3. Where, under the authority of the Medical Acts, the General Council or any Branch Council direct the erasure of the name of any person from any register, the name of that person shall not be again registered in any register except by direction of the Council which directed the erasure, or by order of a court of competent jurisdiction.

4. If the General Council think fit in any case they may direct any Registrar to restore to his Register any name erased by him therefore, and the Registrar shall restore the same accordingly.

5. Section fourteen of the Medical Act (1858) is hereby repealed, but this repeal shall not affect the past operation of that section, or anything already done under it, or invalidate any existing register, order, or regulation kept or made under it, or affect any proceeding or thing commenced under it, or the power of the General Council to make any order in relation thereto; and every such proceeding or thing may be carried on and done as if the said section had not been repealed.

6. Each Registrar shall keep his Register correct in accordance with the provisions of the Medical Acts and the general regulations and special directions of the General Council (whether made or given before or after the passing of this Act).

7. Each Registrar shall erase from his register the name of any person deceased.

8. Each Registrar shall from time to time insert in his register any alteration in the address or qualification of any person registered.

9. In the execution of the aforesaid duties, each Registrar shall act on such evidence as in each case appears to him sufficient, subject to any regulations of the General Council.

10. Each Registrar may erase from his register the name of any person who has ceased to practise; and in order to the better execution of that duty, each Registrar may send by post to any person Registered in his register a registered letter, addressed to that person according to his registered address, inquiring whether or not he has ceased to practise, and if the Registrar does not, within *three months* after sending such a letter, receive any answer thereto from the person to whom it is sent, he may, within *fourteen days* after the expiration of the said period of *three months*, send by post to that person another registered letter, addressed to him according to his registered address, referring to the first letter and stating that any answer thereto has not been received by the Registrar, and if the Registrar does not within *three months* after sending such second letter receive any answer thereto from the person to whom it is sent, that person shall, for the purpose of the present section, be deemed to have ceased to practise; and the name of any person shall not (without his consent) be removed from the register on the ground of his having ceased to practise, except in pursuance of the provisions of the present section. Provided that a person whose name has been erased from the register, with his consent, on the ground of his having ceased to practise, shall not be liable to any penalty under this section, by reason of his being engaged gratuitously in the cure or treatment of any disease or injury.

11. Every person shall be entitled to be registered under the "Medical Act, 1858," who is qualified as follows:

First. Is at the time at which he applies to be so registered legally possessed either of one of the qualifications described in Schedule (B)* of this Act, or of some other foreign or colonial diploma obtained in the opinion of the General Council after such course of study and such examination as guarantee to their satisfaction the possession by the applicant of sufficient knowledge and skill for the efficient practice of medicine and surgery.

Secondly. Has resided in the United Kingdom for a period of not less than twelve months immediately previous to making his application.

Thirdly. Has not been guilty of any offence which according to the laws of the country to which he belongs would disentitle him to practise medicine and surgery, or which according to the "Medical Act, 1858," would enable the General Council to strike his name off the Register.

12. If it appears to the Privy Council, on the representation of the General Council, that any qualification other than those described in Schedule (A.) to the "Medical Act, 1858," and in Schedule (B.) to this Act is granted by any University, College, or Body in the United Kingdom or elsewhere, after such a course of study and such examination as guarantees to the satisfaction of the General Council and Privy Council that any person to whom such qualification has been granted possesses the requisite knowledge and skill for the efficient practice of medicine and surgery, it shall be

* Schedule B. includes the Diplomas of certain eminent Foreign and Colonial Schools of Medicine.

lawful for the Privy Council (in the case of any qualification granted by any University, College, or Body in the United Kingdom) to direct by order that every person holding such qualification shall be entitled to be registered under the "Medical Act, 1858," in the same manner and with the like effect as if the qualification were described in the Schedule (A.) to the "Medical Act, 1858," and (in the case of any qualification granted by any university, college, or body elsewhere than in the United Kingdom) to direct by order that every person holding such qualification shall be entitled to be registered under the "Medical Act, 1858," in the same manner and with the like effect as if the qualification were described in the Schedule (B.) to this act.

13. The provisions contained in sections 20, 21, and 22 of the "Medical Act, 1858," shall apply to any qualification which in pursuance of this act entitles persons to be registered under the "Medical Act, 1858."

14. The degree of Bachelor of Surgery conferred by the University of London shall, for the purpose of enabling any person to be registered under the "Medical Act, 1858," be deemed to be one of the qualifications described in Schedule (A.) of that Act.

UNREGISTERED PERSONS.

15. Section forty of the Medical Act (1858) is hereby repealed; but this repeal shall not apply to or in respect of any offence committed before the passing of this Act, or affect any proceeding pending at the passing of this Act.

16. If any person practising Medicine or Surgery, or engaged in the cure or treatment of diseases or injuries, not being registered under the Medical Acts, takes or uses any of the designations enumerated in Schedule (A.) to the Medical Act (1858) as amended by Schedule (B.) to this Act, or by any other of the Medical Acts, or the designation of Physician, Surgeon, Doctor of Medicine, or Apothecary, or any other designation used by or used to distinguish duly qualified practitioners of medicine or Surgery, or any class thereof, or the designation of professor of medicine or of professor of surgery, he shall for every such offence be liable on summary conviction to a penalty not exceeding £20.

SAVING.

17. Nothing in this Act shall prejudicially affect any occupation, trade or business, rights, privileges, or employment, expressly saved from the operation of the Medical Act (1858), or affect the rights or interests of any person or class of persons expressly exempted or protected by any provision of any of the Acts described in the Schedule to this Act.

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

THE prominent characteristics of the annual *soirées* of the Pharmaceutical Society have ever been a remarkable business-like energy and abundance of attractions. The society's house in Bloomsbury-square is usually crowded on these occasions with objects of novelty, interest, and utility. The *soirée* on Tuesday was no exception in all these respects to the former *conversaciones* of this institution, and the company, numbering considerably over 400 guests, who were received by the President, G. W. Sandford, Esq., evinced their gratification with the provision made for their entertainment. The display of microscopes was large in number beyond precedent, nor were the objects shown by them unworthy of such a remarkable accumulation of instruments. Messrs. Ross, Smith and Beck, and Browning had some of their best, as well as selections of their objects. So also had the Messrs. Horne and Thornthwaite, Murray and Heath, Ladd, Collins, Elliott, Wheeler, &c. Mr. Casella of Hatton-garden, showed a very ingenious cruciform sun-dial, and Mr. Saunders of Potter's Fields, some fine samples of ivory, while the walls of more than one of the apartments were literally covered with Mr. Jardine's admirably mounted dried plants. Some very fine pictures were also lent by Mr. Vokins. Mr. Morson also lent some valuable paintings. Mr. Tennant exhibited a valuable series of crystals and gems—namely, diamonds, corundum, spinel, ruby, garnet, topaz, tourmaline, rock crystal, beryl, &c. There were also amongst the ornamental part of the exhibition some noble vases by Messrs. Copeland and Phillips. The Stereoscopic Society contributed a full-length portrait of Chang the giant—the largest photograph that has yet been taken. Many of the remarkable objects which recent

science and invention have brought forward found places in the various rooms; amongst these we observed Gisborne's pneumatic signal apparatus, Dr. Bence Jones's animal quinioidine, Mr. Ansell's fire-damp detector, the graphotype—of which invention Mr. Fitzcook exhibited some new specimens from the brush of those famous artists John Gilbert and John Tenniel. Dr. Thudichum also displayed by the lime light a series of tapeworms, cysts, and other parasites and the living trichina spiralis itself; and Mr. Larkin blinded for some seconds the eyes of the audience by one of the most marvellous flashes of light produced by the explosion of chlorate of potash and magnesium—a flash that Mr. Debenham utilised most effectually, by taking a very successful instantaneous photograph of the scene.

The greatest novelty of the evening was Dr. Redwood's new process for preserving fresh meat. It is simply to dip the joint in melted paraffine; the hot liquid drives out the air from the tissue, and on the joint being withdrawn and put in colder paraffine an additional layer coats it, and a thick white envelope is completed. Specimens have been sent in ships to various foreign parts to test the process, but none of these examples have yet had time to return for that necessary examination which is requisite to stamp a permanent commercial value on the method. The refreshments were on an abundant scale, and Mr. Shepherd supplied *ices ad libitum* to all comers from one of Carré's large artificial freezing machines. These machines excited much attention in the late International Exhibition, and there is now a large exportation of them to India, Mexico, Cuba, and other tropical countries.

POLLUTION OF RIVERS.

THE Commissioners appointed to inquire into the best means of preventing the pollution of rivers have issued their first Report, which relates to the Thames. They have examined this stream, and inquired about its condition and prospects of improvement at most of the important towns between Oxford and London; also at Croydon and South Norwood. The conclusions to which they have been led by these inquiries are, briefly, as follows:—That the works intended for the preservation of the Thames as a navigable stream are in a ruinous condition,—some of the locks and weirs being absolutely dangerous; and that the water is polluted by sewage, the waste of paper mills and tanneries (readers can reflect on the meaning of these simple words), to say nothing of what comes from floating carcasses of animals. In short that which everybody knew already is officially affirmed.—to wit, that the metropolitan river is in a filthy condition ere its waters are pumped into our cups, so that Londoners actually consume the sewage of the up-country towns, with all their vast population and innumerable industries. By way of remedying this state of things, the Commissioners propose that the whole river be placed under the superintendence of the Conservancy Board; that this body have added to its number representatives of interests which derive from the upper parts of the stream; that after a period has elapsed sufficient for the alteration of present arrangements with regard to sewage, it shall be unlawful to discharge the same into the river, until it shall have been passed over land, so as to be purified; or for any injurious refuse to be cast into the stream from paper-mills, tanneries, and other works (with which should be included soap, soda, manure, chemical, gas, glue, and the thousand like) between Cricklade and the commencement of the metropolitan sewage system; that the water companies whose supplies come from the Thames, be compelled to pay a rental in proportion to their demands for the article in which they deal,—but, let us add, for which they pay nothing; that powers be given to the Conservatory to embank throughout the valley of the Thames, and execute arterial drainage operations; that a rate be levied by the Conservators on property thus improved. The disgraceful failure of what is called "The Smoke Act,"—designed to prevent pollution of town atmosphere, failure due entirely to the neglect of those local authorities who should have put the law in force,—leads us to hope that an independent body may be intrusted with the management of the Thames.

CASE OF BLACK DEATH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I think it desirable that all cases of *Febris Nigra* of recent occurrence in this city, and duly authenticated by medical observation, should be promptly reported, with a view to the adoption of precautionary measures, I beg to submit the following case, in the practice of Dr. Cahill of Dame-street, who has this day kindly communicated to me the details:—

A young married man, actively engaged in commercial pursuits, healthy and temperate, was, on the morning of last Tuesday week, 8th of May, in his usual good health, and whilst dressing on that morning boasted to his wife of his then robust condition. On the evening of that day, after returning from his house of business in the city to his residence in the suburbs, he had a rigor, and passed a restless night. The following day, about two o'clock, he was seen by Dr. Cahill's assistant, and then complained of severe pains in the calves of his legs, was feverish, but quite conscious, and exhibited no indications of sinking; the hands and feet, however, were covered with dark livid blotches, and on the face and neck was a rash, resembling very closely in tint and general appearance the eruption of measles.

At six o'clock the same evening Dr. Cahill called to see the patient, and found him dead. The body was quite black, not uniformly, but in blotches, and shortly afterwards, he has been since informed, it assumed a still darker hue.

I think, without going further into the details of this case, it is fairly entitled to be classed amongst those of "black death," recently reported in your journal.—Faithfully yours,

T. HAYDEN.

30, Harcourt-street, Dublin, May 21.

THE GRIFFIN TESTIMONIAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—May I ask for a prominent place in your journal for the annexed circular, which has been forwarded to every known subscriber to the "Griffith Testimonial Fund."—Yours obediently,

ROBERT FOWLER, M.D.

145, Bishopsgate-road, May 12, 1866.

"GRIFFIN TESTIMONIAL."

"DEAR SIR,—The design for the above being nearly completed, I am desirous to receive from every individual subscriber to the fund a written intimation, as to whether it would be consistent with his desire and convenience to attend a banquet in London (say about three p.m. in the day), whereto to publicly present the Testimonial to Mr. Griffin.

"I would also respectfully ask each subscriber to forward me, at his earliest convenience, his *Carte de Visite*, having his designation, professional title, and (if a Poor-law Medical Officer) the name of his Union plainly written on the back.

"I have reason to believe that it would be most agreeable to Mr. Griffin to additionally receive an appropriate Album containing the photographs of his friends and admirers.

"Prompt attention to the above will greatly oblige yours faithfully,

"ROBERT FOWLER,

"Treasurer and Hon. Sec.

"145, Bishopsgate-street Without, London, May, 1866,"

TONSILLITIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Referring to the remarks on tonsillitis in Dr. Lyons's clinique last week, I venture to say that if, after free scarification, he try the application of the caustic solution, or, still better thing, tincture of iodine, he will not be disappointed in obtaining good results. I have for many years used a tonsillotome, made by Mr. Millikin, formerly of St Andrew-street, to my suggestion. It is a miniature of the midwifery perforator used, and can be handled most freely in operations of the kind with the mouth.—I am, dear Sir, yours truly,

JAS. MARTIN.

Portlaw, May 3, 1866.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 10th inst. :—

Atkins, Thomas Dealtry, Calcutta.
 Bernard, David Edward, Bath.
 Bush, Charles Arthur, Bath.
 Bush, John Dearden, Newcastle-on-Tyne.
 Creswell, Richard, Lewisham.
 Farwell, James Win. George, St. Martin's, near Liskeard.
 Fluder, Arthur Bisdall, Lymington.
 Hanks, George Thomas, Clapham.
 Harwood, Alfred, Cambridge.
 Maxwell, Edward Cleaver, Barnstaple.
 McCarthy, Jeremiah, London Hospital.
 McDonald, William, M. D. Edin., Edinburgh.
 Moore, William Henry, Liverpool.
 Mousley, George William Atherstone, Warwickshire.
 Newman, Adam Perry, M. B., Dub., Cork.
 Robinson, Richard Hoyt, Manchester.
 Sawyer, James, Birmingham.
 Sedgwick, Henry, St. John-street.
 Tindale, Wentworth Raynes, Peckham-rye.
 Waller, Arthur, Milner-square.
 Wall, Reginald Bugh, Baywater.
 Whitwell, John Maude, Kendal.

At the same meeting of the Court, Mr. Robert Atkinson of H.M.S. *Prince Consort*, passed his examination for Naval Surgeon. This gentleman had previously been admitted a Member of the College, his diploma bearing date April 17th, 1854. It is stated that of the 76 candidates who offered themselves for examination, 13 failed to acquit themselves to the satisfaction of the Court, and were consequently referred back to their hospital studies for six months.

The following members of the College, having been elected Fellows at previous meetings of the Council, were admitted as such on the 14th inst. :—

Buncombe, Charles Hope, York-place, Bow-road; diploma of membership dated May 29th, 1840.
 Dalton, Henry Gibbs, Georgetown, Demerara; diploma of membership dated Feb. 19th, 1841.

The following gentlemen passed their primary examinations in Anatomy and Physiology, on the 15th inst., and when eligible will be admitted to the pass examination :—

George Ridley Milles, Edward Lawrie, William Jebson Stothard, Charles Henry Denny Robbs, John James Frazer, George William Smith, Owen Thomas Evans, John Williams Pring, David Johnston, David Owen Fontaine, Charles Henry Lyster, Edward Bray Fellow, James Hutton, Wilkie Hildley, Benjamin Franklin, Frederick Edwin Verne, Thomas Henry Lovegrove, Edward Cruikshank Malloch, Frederick Knowles, George Charles Coles.

Of the 33 candidates who offered themselves for examination no less than 14, it is stated, failed to acquit themselves to the satisfaction of the Court, and were therefore referred back to their anatomical studies for three months.

ROYAL COLLEGE OF SURGEONS, IRELAND.—The annual election of Council will take place on Monday week next, June 4th, from one to three o'clock. In addition to the present Councillors, Drs. Elliott and Mapother of Dublin, and Dr. Johnson of Kilkenny, have announced their intention of submitting their claims to the Fellows of the College.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received certificates to practice, on the 10th inst. :—

Baron, Thomas, Uleby, Lincolnshire.
 Evans, Owen, Pandy Trefriw, near Conway, N. Wales.
 Howse, Frederic, Alexander-road, Kilburn-park.
 Leggatt, Alfred John, William-street, Lowndes-square.
 Lucas, George Burwell, Cambridge.
 Mudd, Frederic Charles, West Pallant, Chichester.

ROYAL DUBLIN SOCIETY—Monday, May 28, eight p.m., Dr. Mapother—"Labourers' Dwellings, the Success and Failures of Efforts to Improve them by means of Inspection, Loans, and Public Companies, and the expediency of extending to Ireland the compulsory principle in their erection and maintenance."

THE Prince of Wales is to lay the foundation stone of the Staffordshire Infirmary on Monday, June 25th.

A NEW disease has been described in the *Journal de Pharmacie*, to which Dr. Callani gives the name of "acetone-mie." It is thought to be produced by the formation of a

chemical compound called acetone in the system, which compound arises from the fermentation of organic matter in the stomach.

The police of New York are taking means to detect the milkmen who put water into their milk, and are publishing their names in the newspapers.

GOUNOD'S "Ulysses," which has never yet been heard in this country, will form the principal attraction of the concert to be given in aid of the Hospital for Consumption at St. James's Hall, on the 8th of next month.

The city engineer of Zurich has just published a book on the sewage of towns, "Ueber Anlage Stadtrischer Abzugskanäle und Behandlung der Abfallstoffe aus Städten," which is highly spoken of as exhausting the subject.

At a meeting of the governors of the London Fever Hospital, held on the 11th inst., Dr. Murchison and Dr. Buchanan were presented with very handsome silver vases, in testimony of the unwearied devotion and eminent skill with which they discharged their professional duties during an epidemic of unparalleled severity and duration.

CATTLE PLAGUE QUARTERLY RETURNS.—A few days ago a Parliamentary paper was issued containing returns of the number of farms, &c., affected, and of the animals attacked, killed, died, and recovered, from the commencement of the disease to the 30th of September, 1865, and the 30th of December, 1865, respectively. According to this return the number of animals attacked in England, Wales, and Scotland in the period mentioned was 76,006; killed, 13,906; died, 43,812; and recovered, 7354. The number of farms, &c., affected was 9954.

The cholera is disappearing from Guadaloupe, after killing 10,856 out of a population of 149,107.

WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING MAY 19TH, 1866

By J. H. STEWARD, Strand, and Cornhill, London.

Notices to Correspondents.

The Royal Institution.—The notice has been received.
 Mr. J. L.—The subject is under consideration.
 Amicus.—We have no experience of the results of the treatment in question.
 A. B.—The question is alluded to elsewhere.
 T. F. (Liverpool).—If the youth is in other respects sufficiently well prepared, and can devote about six months to study between leaving school and the period fixed for the examination, he should present himself for the Matriculation of the University of London. The examinations are held twice a year.
 The Treatment of Cholera.—We are often asked, both in our private and public capacity, what is the best treatment to be pursued in case either of a fully developed attack of cholera, or of a condition of looseness of the bowels which has frequently preceded the disease. Without offering any plan of specific treatment, we think that the premonitory diarrhoea when it exists ought to be checked by those remedies which are commonly used for the purpose; and without in any way denying the great ability displayed by a well-known London physician in advocating what has been termed the climatic treatment, we believe that the administration of castor-oil is about the worst plan that can be adopted. When the use is fully developed, we know of no better course than to endeavour to rouse the flagging energies of life by the administration of stimulants, but this plan often fails.

Appointments.

E. BRYAN, M.R.C.S.E., Assistant House-Surgeon to the Public Hospital and Dispensary, Sheffield.
 Dr. BURROWS has been appointed one of the Consulting Physicians of the Briton Medical and General Life Association, in the place of Dr. Babington, deceased.
 E. ELLIOTT, M.D., Honorary Surgeon of the Royal Portsmouth, Gosport, and Portsea Hospital.
 H. W. FAGOE, M.R.C.S.E., House-Surgeon to the Royal Free Hospital, vice John Haskney, M.R.C.S.E., resigned.
 R. S. P. GRIFITHS, M.R.C.S., L.R.C.P.L., House-Surgeon at St. Mary's Hospital.
 F. J. LILLEY, L.R.C.P.Ed., M.R.C.S.E., Senior Medical Officer to the Life Investment, Mortgage, and Assurance Company, New Bridge-street, Blackfriars.
 T. P. PICK, M.R.C.S.E., Curator of the Anatomical Museum, St. George's Medical School, vice W. H. Dickinson, M.D., appointed one of the Assistant-Physicians to the Hospital.
 Mr. W. QUIBELL, Dispenser to the General Infirmary, Sheffield.
 G. E. SHUTTLEWORTH, B.A., M.R.C.S.E., Medical Associate of King's College, London; Resident Medical Officer to the Kilburn, Maida-vaile, and St. John's-wood Dispensary.
 S. WILKINSON, F.R.C.S.E., has been appointed an Assistant-Surgeon to the Central London Ophthalmic Hospital, Gray's-inn-road.
 W. J. COUSINS, M.D., one of the Medical Officers for the Royal Portsmouth Hospital.
 W. HARDIN, L.Q.C.P.I., Medical Officer of the Royal Portsmouth Hospital.
 A. J. POLLOCK, M.D., Physician to the Foundling Hospital.

Vacancies.

POOR-LAW MEDICAL VACANCIES.

Croydon Union.—Fourth District; area 2130; population 13,200; salary £100 per annum.
 Hastings Union.—Third District; area 8144; population 1552; salary £40 per annum.
 Knaresborough Union.—Harrogate District; area 13,069; population 6669; salary £35 per annum.
 Warwick Union.—Workhouse; salary £64 per annum.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

BIRTHS.

BETH.—On May 10, at the Royal Naval Hospital, Plymouth, the wife of R. Beth, M.D., Deputy Inspector-General of Hospitals, of a son.
 CREGEEN.—On May 15, at Upper Brent Cottage, Blackheath-hill, the wife of J. J. Cregeen, M.D., of a daughter.
 MUNRO.—On May 11, at Kinross, the wife of R. Munro, L.F.P.S.Glas., of a daughter.
 MURRAY.—On the 4th inst., at Newgate-street, Newcastle, the wife of John C. Murray, of a daughter.
 WOOD.—On May 9, at Ashton-under-Lyne, the wife of Herbert Wood, M.R.C.S., of a son.

DEATHS.

ALEXANDER, J. T., M.R.C.S.Edin., at 2, Church-hill, Morningside, Edinburgh, on May 13.
 BEABANT, R. H., M.D., at Marlborough-buildings, Bath, on May 13, aged 85.
 HARVEY, W. H., M.D., at Torquay (Professor of Botany in the University, Dublin), on May 15, aged 55.
 STEVENS, J., L.R.C.P.Edin., at 26, Bloomsbury-square, on May 16, in the 47th year of his age.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

Hospital Reports.

SIR PATRICK DUN'S HOSPITAL.

REMARKABLE CASE OF CEREBRO-SPINAL ARACHNITIS.

Under the care of Professor BANKS.

RALPH PECTOR, aged 14, a deaf-mute, was admitted into Sir P. Dun's Hospital, under the care of Dr. Banks, on May 21, 1866. From those who brought him the following particulars were obtained:—

He had formerly been an inmate of the Claremont Deaf and Dumb Institution; but for the last year had been bound as apprentice to a shoemaker residing in Stafford-street, and it appeared that while under this man's observation he was a most diligent and attentive lad, rapidly receiving instruction in matters concerning his trade, and in the possession of the most perfect health up to commencement of his illness—that is, the day before his admission to hospital. On this day (May 20th) he was observed about noon to suddenly throw himself down on his bed, and in a short time to vomit a thin watery-sort of substance in considerable quantity. He now lost all consciousness, nor did he afterwards take the slightest notice of anything about him. He was seen by those about him to clench his fists; he was heard to grind his teeth, and he writhed, as if in a fit, several times, during which he voided his urine involuntarily.

May 21st: On being brought into hospital we observed that he lay on his left side with the thighs flexed on the abdomen, and his head flexed on the thorax; and on attempting to turn him over on his back, and especially to turn his head towards the right shoulder, a certain amount of stiffness of the muscles had to be overcome before this could be accomplished. These movements seemed to cause him considerable pain. The same resistance was found in the eyelids on attempting to separate them. The pupils were equal, neither much contracted nor dilated, and only slightly responded to impressions of light. Both eyes were turned to the left, and could not be made to move by a light placed to the right side. His mouth was drawn to the left side; the filtrum being oblique and pointing also to the left side. When we pressed on his abdomen he suddenly doubled himself up, as if to arrest its further continuance. He moved his left arm and leg about with a certain amount of regularity, slowly flexing, and then rapidly extending the extremity again, nor did he cease these motions until the last day of his life; pulse 120, and small; urine albuminous, and passed involuntarily.

22nd: Pulse thread-like and difficult to count. The same movements of the extremities continue, and the same semi-flexed position assumed.

23rd: The hands, patellæ, and ankles and feet have assumed a deep violet tinge, somewhat patchy about the ankles, but in no part was there extravasation of blood. He now lies extended in bed.

On examination of his urine, it was found to be loaded with albumen, markedly acid, and not deficient in chlorides.

He died at three p.m., the duration of his disease being about three days. (The preceding record was kindly furnished by Mr. Moore, resident pupil.)

Autopsy six hours after death by Dr. Bennett, Surgeon to the Hospital and University Anatomist.—The body retained but little of the livid marking, except on the

lower extremities. In consequence of the diagnosis of cerebro-spinal arachnitis having been made by Dr. Banks, the brain and spinal cord were first examined. The skull being opened with the saw, the brain was found to be deeply congested, the congestion of a deep venous tint.

There was no adhesion between the surfaces of the arachnoid membrane anywhere in the cranium except at the anterior part of the longitudinal fissure, nor was there any accumulation of fluid in its cavity. On raising the brain there was seen to be much semi-purulent lymph in the great subarachnoid space; this effusion was, however, confined entirely on the aspect of the membrane in contact with the pia mater, none being on the free surface. The greenish yellow colour could be traced outwards through each fissure of Sylvius, and so over the sides of the brain, principally along the distribution of the middle cerebral arteries. On raising the posterior lobes of the brain the same deposit could be traced all around the fissure of Bichât, and it spread a short way over the cerebellum and forwards into the velum interpositum. The lateral ventricles contained a turbid and almost purulent serum, which was faintly acid in reaction. Their lining membrane was much congested, the congestion markedly venous in colour. The oval centres showed congestion throughout; there was no cerebral softening. The spinal canal was opened from above down; the membranes were intensely congested close to the skull, and as the bone was removed from the lower cervical region there was found an abundant coating of lymph on the external surface of the sheath; from this down to the sacrum the lymph entirely covered the posterior aspect of the sheath, being in greatest quantity about the very lowest part. So abundant was the lymph in the lower lumbar region that it was difficult to raise the nerves and cord out of the canal from their being almost completely concealed. The cord and sheath having been removed, the sheath was opened, and the same arrangement of the inflammatory effusion found internally as on the outside. The lower end of the subarachnoid cavity was filled with purulent fluid; the anterior face of the cord was intensely congested, but nearly free from deposit; the posterior face from the cervico-brachial enlargement down was covered with green lymph.

The viscera of the thorax were free from any disease, except some amount of serous effusion, most probably effused just previous to death. The abdomen was free from disease, except that the kidneys were congested; the Malpighian tufts could be distinctly seen.

Weight of brain, 3 lb. 7½ oz.; cord, 2 oz.; kidneys, 8 oz. Dr. Banks observed that this case presented the features with which he was familiar when cerebro-spinal arachnitis existed in an epidemic form in Ireland in the year 1846. This terrible disease was first noticed in the Rathdown Workhouse by Dr. Darby of Bray.

There was one point of great interest in this case, and which did not exist to a like extent in any case observed by Dr. Banks, nor did he believe it had been noticed previously—viz., the deep cyanotic hue of the skin.

He had never seen, except in pestilential cholera, a similar appearance.

The boy had been up to the moment of his seizure in the most perfect health, and so it was in the cases in the epidemic of 1846.

The late Dr. Mayne, in his admirable paper on cerebro-spinal arachnitis, published in the *Dublin Quarterly Journal*, says—"In four of the cases at the South Dublin Union, the boys had eaten a hearty dinner and retired to bed in apparent health, when the disease all at once declared itself. In many instances it commences with severe pain in the abdomen, followed by vomiting, and not unfrequently by purging. In the worst cases, these symptoms are accompanied by marked collapse, the extremities are cold and bluish, the pulse is at this time a mere thread, and altogether the disease assumes very much the aspect of cholera."

Dr. Banks said he could bear witness to the accuracy of this description, and to the resemblance of some cases of

this disease to cholera—a fact to which he wished to draw particular attention.

True it is, that the physician who is intimately acquainted with both diseases, could not fall into the error of mistaking cerebro-spinal arachnitis for cholera, but the mistake is quite possible in a case like that now under consideration, and particularly when an invasion of cholera is threatened.

To the experienced eye, although there were symptoms which in some degree resembled cholera, there was absent the "facies cholericæ," which, once seen, can never be forgotten.

Even the extremities, although so closely resembling in colour what is observed in cholera, nevertheless wanted that peculiar wrinkled condition of the skin and the coldness so characteristic of the disease.

In conclusion, Dr. Banks drew attention to the peculiarities which rendered the case worthy of being placed on record. It was unlike the cases of sporadic cerebro-spinal arachnitis, which had from time to time come under his observation, in its severity and rapidly fatal progress, and resembled closely the disease as it appeared in the epidemic form in France in the years 1840, 1841, and 1842, and subsequently in Ireland. The deep discoloration of the skin was also a strange and peculiar feature. Little need be said as to treatment. From the moment the boy was admitted into hospital the lethal character of the disease was obvious. Mercury, blistering, and stimulants were the remedial agents which were directed.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

EMPLOYMENT OF A NEW FEBRIFUGE—CHLORATE OF QUINIA.

Scarlatina Anginosa; Use of Chlorate of Quinia; Rapid Deferescence.—J. M., female, unmarried, aged 18, was admitted into hospital with well-marked scarlatina anginosa. The rash was very fully developed on the chest, arms and legs, of uniform boiled-lobster tint; the pulse was 130 and very feeble, and the patient had a dull heavy look, and complained much of the throat. On examining the fauces, both tonsils, the velum palati, arches of the palate and back of the pharynx, were much engorged, of a deep claret colour, and much distress was experienced at any attempt to swallow. Both tonsils were enlarged and spongy, the crypts being filled with buff-coloured exudation, the right gland being specially engorged. The chlorate of quinia was ordered for this patient in three-grain doses every third hour; in addition to which the tonsils were washed with a 20-grain solution of nitrate of silver, and a gargle composed of chlorate of potash, perchloric acid, syrup and water, was directed to be used frequently during the day. Wine and beef-tea were also liberally allowed. On the following day a very marked improvement in the patient's condition was observable; the pulse had improved in volume and diminished considerably in frequency; the engorgement of the throat had much decreased, and deglutition was performed with far greater ease and freedom from pain. On the fourth day deferescence was well established; the pulse had fallen to 80, the throat was quite restored to a natural condition, and the patient was in all respects convalescent. In two other cases of scarlatina, but of milder form, the chlorate was employed with very satisfactory results.

Protracted Typhus Fever; Supervention of Diphtheria on the 21st day; Use of Chlorate of Quinia; Recovery.—This patient, aged 33, passed through almost all the possible conditions and complications of protracted low typhus. The maculæ became transformed into petechiæ, which continued persistent till towards the close of the case. Involuntary passage of urine and fæces, with diarrhœal

discharges and much tympanitis, formed prominent features of the case for many days; days and nights passed without an hour's continuous sleep, or even rest; constant muttering, attempts to get out of bed, general nervous tremor with constant subsultus tendinum, and tossing of the head from side to side next supervened; the pulse became exceedingly rapid and feeble, and the heart's action assumed the *tic-tac* character, the impulse being imperceptible, and the first sound faint to the last degree of audibility. The most vigorous and well-maintained stimulation by day and night seemed alone to keep the feebly flickering flame of life from being at any moment extinguished. Later on suffocative catarrh was threatened and with difficulty averted, and the bronchial affection overcome. Finally, in the interval of the 21st and 22nd day of the disease, when some slight general amendment had been established, it was found that an extensive diphtheritic exudation of tough buff-coloured matter covered the hard and soft palate, the pillars of the fauces, the tonsils, and all parts of the pharynx within view, extending likewise to the base of the tongue, and forward on the dorsum of that organ to near the tip.

Turning the patient to a strong play of sunlight, fortunately at the time available, Dr. Lyons introduced the index finger of the right hand covered with an extemporized mop of old linen, and carefully swept off the pellicular exudation from all parts within reach; in some situations it was found so tough that the handle of a spoon had to be employed to detach it, as from the half arches of the palate and the base of the tongue. All parts within reach were then carefully mopped with the muriated tincture of iron by a piece of sponge of suitable dimensions tied on the end of an elastic sprig of wood. Dr. Lyons states that for his part he is an advocate for the careful removal when practicable of the pellicular exudation before the use of any topical applications. As in the case under consideration, the exudation, he affirms, often constitutes so complete and so impenetrable a coating to the mucous membrane, that it is, in his opinion, idle to expect beneficial result or any action whatsoever from the strongest local applications, which under these circumstances, cannot possibly reach the mucous surface. In the case in question the pellicle was fully detached by the means employed, the mucous surface laid bare being exceedingly vascular, and here and there shewing bloody dots of minute ruptured vessels. The muriated tincture of iron was now freely applied directly upon the affected surface, besides which the throat was repeatedly gargled with a mixture containing chlorate of potash, perchloric acid and syrup, and with such decided results that no further exudation whatever took place. The patient was further directed to take the chlorate of quinia in about five-grain doses every third hour, according to the following formula:—

℞ Chloratis quiniæ, ʒiiss.
Acidi perchlorici, ʒii.
Syrupi auranti, ʒii.
Aquæ destillatæ, ad ʒviii. M.
Sumat. ʒss. 3tiis horis.

The gargle employed in this and the previous case consisted of two drachms of chlorate of potash, two drachms of perchloric acid, three ounces of syrup and five ounces of water. Under the use of these remedies the patient rapidly improved, and about the 28th day from the first invasion of the fever convalescence began to be fairly established, and continued permanent.

From the powerful oxidising and general stimulating agency of chloric acid, and the influence of quinia as a nervine-tonic, Dr. Lyons has been led to the idea of combining these two remedial agents with the view of obtaining a febrifuge medicine of great potency. Each atom of the chlorate will provide, it may be expected, five available atoms of oxygen from the chloric acid, chl. O₃, while in the perchloric acid, each atom contains seven of oxygen, chl. O₇.

From some half-dozen cases in which he has as yet employed this drug, including Scarlatina, Typhus, the Dip-

theric case above mentioned, and low forms of Pneumonia, Dr. Lyons has obtained results which so far satisfy him of its efficiency and utility, and he invites the co-operation of his professional brethren in testing the value of this salt of quinia in low pyrexial states.

To his friends Professor Aldridge, of Messrs. Bewley and Hamilton's, and to Mr. Tichborne, of the Apothecaries' Hall, Dublin, he expresses his best acknowledgments for the care and trouble they have taken in the manufacture of this novel compound at his request.

MATER MISERICORDIÆ HOSPITAL.

CASE OF ASCITES WITH ANOMALOUS THORACIC SIGNS.

(Under the care of Dr. HAYDEN.)

(Continued from page 334.)

THE following record gives the conclusion and post-mortem examination of a very remarkable case, to understand which clearly, reference must be made to p. 334.

April 6, 1866: Pulse 108, and feeble; copious night sweats; the patient was delirious last night, and now suffers from general soreness rather than pain.

The tenesmus was controlled by bismuth and opium. No change in the physical signs over the left side of the chest.

April 9: Pulse 108, and weak; respiration 48. There is great fœtor of the breath, and the diarrhœa continues notwithstanding the exhibition of gr. iiii. of acetate of lead and gr. ½ of powdered opium after each liquid motion.

Repeat tincture of opium and liquor of bismuth.

April 18. The patient died at 4 p.m., worn-out by suffering, which was partly due to bed sores, and by diarrhœa. Shortly before death she vomited up a large quantity of dark blood.

Autopsy eighteen hours after death.

The body was much emaciated, a large quantity of greenish opaque fluid with flakes of curdy lymph floating in it was found in the peritoneum. The abdominal viscera were all firmly agglutinated to one another and to the abdominal walls by thick layers of false membrane. The parietal peritoneum was throughout coated with a similar layer, as thick as shoe-leather. The liver, which was firmly adherent to the diaphragm by recently effused lymph, rather exceeded in volume the normal size of that organ, and afforded a good example of cirrhosis with granular fatty degeneration, being pale and granular on the surface, and in section devoid of vascularity, and deeply mottled with masses of yellow fat. The spleen was of a dark slate-colour, and at least twenty times its ordinary volume.

The mucous membrane of the large intestine was of a dark chocolate colour, and softened.

The pelvic organs were all in a healthy condition; the ovaries were not diseased. The pericardium did not contain any fluid. The heart, which was of the ordinary size, presented a good deal of superficial fat. Both pleural cavities contained fluid. On the right side this was small in quantity, and of a pale green colour, but clear; but on the left side it nearly filled the pleura, and was of the colour of whey. The right lung was slightly emphysematous on its anterior margin, and hypostatically congested posteriorly, but was otherwise in a normal condition. The left lung was adherent to the anterior wall of the chest superiorly, and to the cone of the pleura. This portion (the superior lobe) of the organ was of the ordinary volume, and was resonant on percussion; but the inferior lobe was compressed into the posterior inferior portion of the pleural cavity, where it was bound down, and generally coated over by a thick layer of false membrane. It was much reduced in volume, solid, and dull on percussion. The tympanitic resonance occasionally present beneath the left clavicle during the patient's last illness, as previously noted, and which led to so much speculation in regard to its cause, was manifestly due (for there was no other cause to give rise to it) to the presence here of the superior lobe

of the lung, where it was confined by adhesion and subjected to varying pressure, according to the amount of the pleural effusion, which occupied the lower portion of the cavity. When the liquid effusion increased, or the diaphragm was pressed upwards by the ascites, it caused partial stasis of air in the superior lobe of the lung, which then yielded a tympanitic sound; but under opposite circumstances, and when it was allowed to expand by removal of pressure from below, it yielded resonance, and a respiratory sound, exaggerated only because of the attachment of this portion of the lung to the anterior wall of the chest. Under the microscope, and examined with a power of 222 L., the hepatic substance was devoid of blood, the hepatic cells were gorged with fat globules, which, in most instances, rendered the nuclei invisible. Large oil globules were dispersed over the field. The colouring matter of bile was present in very minute quantity.

The disease of the liver, which was the primary affection in this case, consisted in cirrhosis with fatty degeneration.

Dr. Hayden exhibited the morbid specimens above described to the Pathological Society on the 21st April, 1866

A CLINICAL LECTURE

ON THE

TREATMENT OF TUBERCULAR PHTHISIS.

Delivered in the Theatre of the Cork County and South City Infirmary, on the 27th April, 1866,

By W. O. TOWNSEND, M.D.,

SENIOR PHYSICIAN TO THE INFIRMARY.

WE proceed this morning to the consideration of the treatment of tubercular phthisis.

During the last four lectures we were occupied, I trust profitably, with the consideration of this fearful disease, which, unfortunately, owing to its great prevalence, our hospital affords you ample opportunities of investigating in its different stages.

To some of you, I have no doubt, there appears to be a great amount of sameness in the several cases, and many wonder how little in the shape of medicine, I order for those under my charge; but the truth is, gentlemen, the older we grow, the less faith we have in physic; and I have no hesitation in telling you that the medical management of consumption pre-eminently consists in a liberal and judicious diet, in residence in well ventilated apartments, where there is a constant and fresh supply of unbreathed air; in exercise in the open air, I would almost say in all weathers, taking due care at the same time that your patient is warmly clad. In my opinion, this plan will do more to prevent the development or growth of tubercle than any or all the medicines of the Pharmacopœia.

But you will not, I hope, misunderstand me or think for one moment that I undervalue medicines when judiciously used, but I wish, now at the close of our winter session, and after the careful consideration we have given this subject, that you should have correct notions as to the treatment of this terrible disease.

Doubtless you have often been surprised, as I pass from bed to bed, at the apparently little variety in my treatment; and I can almost fancy I hear you say "always the same"—cod-liver oil, iron, opium—and you are to a great extent right, gentlemen. You have great advantages over your fathers in the profession. You are now in a position, if you will use it, to reap the great harvest of their experience; and I venture to assert that in no disease is that harvest more abundant. Great as the advantages are that we have derived from the glorious discoveries of Laennec, they are as nothing when compared with those which an enlightened pathology has conferred within a very few years on the treatment of tubercular diseases. It is quite true we owe to him and others the knowledge of those physical signs whereby we are enabled to diagnose with such painful certainty the presence of tubercular disease of the lungs; but it is equally true that we are

deeply indebted to Bennett, Thompson, and a host of others who have based the treatment of this disease on true principles derived from an accurate knowledge of pathology. To the first class we owe the great debt of teaching us how to diagnose during life, and after death, the ravages of this fearful malady; from the latter, we learn that our efforts should be directed—*first*, to check the tendency to the disease, and *next* to arrest or cure it in its progress. It is truly deplorable that even at this present time such erroneous notions should be held as to the treatment of this disease. Forgetful or ignorant of the cause, it is too much the habit of many practitioners to devote all their energies to what is in reality not the disease but its result or effect; and the unfortunate patient is made to swallow any amount of cough mixtures, to submit to any amount of blistering, with an occasional leeching—a plan of treatment which might be allowed if it did no harm, but which, tending as it most assuredly does, to the further developing of the disease, cannot be too strongly deprecated.

Of all the constitutional maladies that I am acquainted with *there is none that more can be done for than tubercular phthisis*. It is now an admitted fact that in the very early stage, even where the constitutional tendency is largely inherited, a great deal may be done for the patient, even if he be not completely cured; and there is little doubt that even in the second and third stages of the disease, a judicious treatment will often prolong life for several years. It is well for you, then, to study carefully the principles that should guide you; and I may here take the liberty of reminding you of what I have so frequently called your attention to at the bedside, *that every case of tubercular phthisis has its own natural history, and must be treated on its own peculiar merits*. Unfortunately, in the great majority of cases of tubercular phthisis we do not see the patient until the disease is somewhat advanced; in such the chances of cure will be in the majority, in proportion to the amount of lung injured; not that I wish you to understand by any means, that where a portion of lung is engaged, that person must of necessity die. On the contrary, I have seen and known several, where there could be no reasonable doubt of a large amount of lung being engaged, recover perfectly. Pulmonary consumption is entirely a disease of debility, whether it be inherited or acquired; and the treatment of it in every stage appears to me to be "*support*."

Now, there are two classes of patients which present themselves to us from time to time. Among the *first* we find those who are surrounded by every luxury that wealth can produce; the *second* includes those who are exposed to every privation, who are ill-fed, ill-clad, living in badly ventilated apartments, and eking out a miserable existence. The only wonder in such cases is that they so long resist the development of disease.

I have already told you that it is a disease of debility, and it now becomes my duty to tell you from my own practical experience how you can best remedy that state of system which leads to the growth of tubercle.

First, and above all, I recommend that the patient should breathe a pure air. I find that within the last twelve months there were admitted into the Workhouse Hospital of this (Cork) Union 184 males suffering from tubercular phthisis. I have paid some attention to this important subject, and I find that they are principally composed of tradesmen and indoor servants; while cab-drivers, and those whose occupations keep them constantly in the open air, seldom suffer. Again, I have observed that consumptive patients who remain constantly in hospital, where they are well fed and carefully preserved from changes of temperature, succumb to the disease more readily than those who after a short stay leave, often badly clad, to resume their ordinary avocations. I need say no more to prove to you how indispensable is a pure air for the consumptive patient.

The next point to be considered is *the regulation of their diet*. A consumptive patient should be well fed, and his food should be easy of assimilation; meat, eggs, porter,

wine, butter-milk, should be used; and his diet should be so arranged that instead of giving him two or three meals daily, he should have five or six. I emphatically state that no consumptive patient should be allowed to remain longer than four, or at furthest five hours without food. He should have food late at night and very early in the morning, and some nutritious drink should be placed at his bedside for the night, should he wake.

I now pass to the medical treatment. If a consumptive patient has a fair appetite and digests his food, you had better take care you don't destroy his appetite by the use of what are commonly called expectorants, cough mixtures, sedatives, &c. &c., which instead of doing the unlucky patient good, do him an immense amount of mischief. If, on the other hand, his appetite be bad, take care you don't overload his stomach; give him bitter tonics, quinine, strychnine, and such medicines as will have the effect of bracing up his system, and gently stimulate the relaxed mucous membranes; above all, avoid, unless absolutely called for by bronchitic or pneumonic complications, blistering, leeching, application of iodine, &c. &c.—a system of practice which cannot be too warmly deprecated, as evidencing an unpardonable amount of ignorance of the pathology of the disease; for you should always have before your eyes that your treatment must be directed to remedy that state of system which leads to the further separation or growth of tubercle, taking little heed of that which is already formed.

Of all the medicines introduced to the profession for the improvement of the general health, and therefore for the treatment of pulmonary consumption, none are so conspicuous as cod-liver oil and iron. These, either separately or together, appear to exert a greater influence in arresting the state of system which leads to the growth of tubercle than any other known remedies. I have not time nor inclination to enter into the different discussions as to how they produce such remarkable effects, but that they do so is beyond all reasonable doubt. The use of cod-liver oil is indicated in all stages of the disease, and as there can be no doubt that the bronchitic, pleuritic, and pulmonic complications, which so frequently present themselves, are altogether dependent on the unhealthy condition of the blood, I see no reason why its use should be discontinued during their presence.

In the latter stages of this disease you will find that the various preparations of opium, in one or other of its forms, allay pain, restrain the cough, check diarrhoea, produce sleep; and, in hopeless cases, promote *euthanasia*, by soothing the dying moments of the poor sufferer.

Abstracts of the Scientific Societies.

GEOGRAPHICAL.—May 14.—"On the Geographical Position of Yarkund and other places in Central Asia," by Capt. T. G. Montgomerie, R.E.—"On a Visit to Daba, in Thibet," by Capt. A. Bennett.—"On a Journey to the Western Shore of Volcano Bay, in Yesso," by Commander Forbes.

GEOLOGICAL.—May 9.—President, in the chair.—The Hon. J. Abercromby, Messrs. E. Davis and E. St. John Fairman were.—The following communications were read: "On a new Species of *Acanthodes* from the Coal-shales of Longton," by Sir Philip de M. Grey Egerton, Bart.—"A Sketch of the Gravels and Drift of the Fenland," by Mr. H. Seeley.—"Additional Observations on the Geology of the Lake Country," by Prof. R. Harkness and Mr. H. Nicholson. With a note on the Trilobites, by Mr. J. W. Salter.—"On the Lower Silurian Rocks of the Isle of Man," by Prof. R. Harkness.

CHEMICAL.—May 3.—Dr. W. A. Miller in the chair.—The proposal of the Council relative to the admission of Foreign Members resulted in the election of Prof. Rammelsberg, Dr. W. Gibbs and Prof. Welzien.—Messrs. J. J. Lundy, J. Robinson and M. Hall were elected Fellows.—Dr. J. H. Gladstone read a paper, entitled "Notes on Pyrophosphodiamic Acid," which supplemented an account already presented to the Society by the late Mr. Holmes and the author.

Foreign Medical Literature.

CASE OF ANEURISM OF THE THORACIC AORTA.

Communicated by H. HIRSCHSPRUNG, M.D.

Translated from the *Ugeskrift for Læger*, Copenhagen, December 9, 1865, p. 425.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.,
HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE
NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY
OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURIS-
PRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

The descending thoracic aorta lies, as is well known, on the left side of the bodies of the vertebræ, but approaches, as it runs down towards the aortic opening in the diaphragm, more and more to the middle line. In this route it is crossed by the vena semi-azygos which runs behind it, while the left bronchus and the pericardium lie before it; to the left the vessel is contiguous to the corresponding pleura, and on the right side run the œsophagus, the thoracic duct, and the vena azygos. At the lower extremity, from the eighth thoracic vertebra, the œsophagus lies in front of the aorta, coming forward to pass through the œsophageal opening, and in this place it possesses a great degree of mobility, being accompanied, as it were, with a mesentery composed of lamina mediastini, with intervening, wide-meshed connective tissue, increasing in breadth downwards.

It is easy to foresee that an aneurismatic dilatation of the artery may eventually prove dangerous, from its vicinity to any of the organs just mentioned, and experience has verified this. This is not the place for an opinion based upon statistics as to what organs are most exposed to pressure and destruction or perforation with subsequent, and usually fatal, hæmorrhage. I shall state only that the left bronchus and the left pleura, perhaps rather as the result of preconceived opinion, are mentioned by most writers as the organs which most frequently come into collision with aneurism of the descending aorta, and into which the latter most frequently empties itself; that the œsophagus and the right pleura do not seem to be much behind in this direction; that partial destruction of the dorsal vertebræ is particularly frequent, and that we have sometimes seen the aneurism discharge itself into the spinal canal; that the result of obliteration of the venæ azygos and semi-azygos has been witnessed in the form of a highly developed vein on the thoracic wall, and that Laennec (Édit. Andral 3.439) mentions, that he once saw an aneurism of the descending thoracic aorta, which had produced destruction of the ductus thoracicus, swelling of the lymphatic system, and probably death by inanition. That the œsophagus, notwithstanding its situation, does not occupy a more prominent place in the series, must certainly be ascribed to its great mobility, by the aid of which it is capable of, to a certain extent, as it were, evading the danger.

But the termination, to which we have at present to direct our attention, is bursting of the aneurism with evacuation of its contents into the connective tissue. This mode of rupture seems to be, so far as the mediastinum is concerned, exceedingly rare. I shall mention what I have found stated by some authors upon this point. Grissolle (1850, t. ii., p. 230): "When the aneurism opens into the pleura, the pericardium, the pulmonary artery, the heart, the *mediastinum posticum*, death occurs instantaneously, or at least very soon. But the cause cannot be ascertained until the body is opened." Zehetmayer (*Die Herzkrankheiten*, 1845, p. 386) expresses himself as follows:—"The aneurism connects itself to the left bronchus, and opens for the most part into this, into the pulmonary parenchyma, or into the left thoracic cavity, more rarely

into the œsophagus or into the *mediastinum*, when it has developed itself on the right side of the aorta. Andral (*Cours de pathologie interne*, 1848, t. i., p. 384) communicates the following case:—

"In another case the rupture took place into the *mediastinum posticum* in a woman, who had presented symptoms only of a slightly advanced disease of the heart. She had oppression; the action of the heart was tumultuous and very quick, the pulse was intermitting, the face was livid. She had never suffered from dropsy. Repeated bleedings and digitalis in powder had procured considerable relief. The evening before she was to leave the hospital, she suddenly uttered a piercing cry, grasped her chest with her hands, and was dead. The *mediastinum posticum* was found on dissection filled with an immense quantity of blood, derived from the aorta; the walls of the left ventricle were hypertrophied."

That this mode of rupture occurs only rarely, appears also from statistical reports. In Schmidt's *Jahrbücher*, 1861, p. 237, P. Niemeyer has collected a series of forty-nine cases of aneurism of internal arteries; twenty of these terminated in rupture, but rupture into the connective tissue of the *mediastinum* is not mentioned. In the volume of the year-books published this year, the author has drawn up a second series of not less than 100 fresh cases. Fifty-seven times fatal rupture ensued, and according to the table two of these took place into the *mediastinum* (Nos. 32 and 38). But if we examine these two cases more closely, we shall find that the first (taken from the *Gazette des Hôpitaux*, 1859, No. 96) was only incorrectly included. The second (*Medical Times and Gazette*, March, 1861, p. 251.) is briefly as follows:—

"A powerfully-made man, aged 62, who had never been under medical treatment, had fallen suddenly in the street and died soon after. On dissection the ascending aorta was found to be dilated and highly atheromatous; the transverse aorta was dilated into a large globular swelling, about the size of a large orange; the descending aorta was also atheromatous. The aneurism had burst into the *mediastinum posticum* through an opening as large as the tip of the finger. A sanguineous tumour had here formed, which had secondarily perforated the right pleura, in which was found more than two pounds of coagulated blood. The heart was displaced downwards and to the left side."

These few remarks are the result of research upon the subject in the writings of very many authors; but they of course lay no claim to any completeness. Thus much seems to be decided, that rupture into the connective tissue is an extremely rare termination to aneurisms of the thoracic aorta. In interesting contrast to this, such a result is very general in aneurisms of the abdominal aorta. In a recently published work (*Ueber das Aneurysma der Bauch-Aorta*, Berlin, 1865, p. 48) Lebert shows, that the discharge of an aneurism into the retro-peritoneal connective tissue is very common, and that in sixty-nine cases with rupture it occurred not fewer than eleven times, but so that only in fifteen cases was an extensive and rapidly fatal extravasation produced. In aneurisms of external arteries the same process may occur, but as it seems, only rarely (Nélaton, *Éléments de pathologie*, t. i., p. 453). We then no longer feel any defined tumour, but a diffuse swelling of the limb and sometimes fluctuation, producing the greatest resemblance to an extensive and deep phlegmon, with which such a tumour has been confounded. Vidal and Broca (*Des Anéurysmes*, 1856, p. 67) speak of the same possibility, the first named (*Traité de pathologie ext.* 1, p. 647) adding as a favouring element, that the aneurism is only small.

Reserving to myself to revert to some points in what I have already quoted, I shall now report the case which has been the starting point of the present communication.

Jane Sörensens, aged 34, married, admitted on the 4th October, 1865, into Frederiks Hospital. She was confined once many years since, and had subsequently menstruated regularly. The patient, who lived under ur-

happy domestic circumstances, had been ill for more than six months, suffering constantly from oppression in the epigastrium, especially after meals, from pain between the scapulæ and in the right side of the chest, symptoms which had been treated as hysterical. Latterly her state had become worse, vomiting having supervened, she therefore sought admission to hospital. Two hours before she came in, immediately after eating some porridge, she was seized with a feeling of weight in the stomach and nausea. To encourage vomiting she thrust her finger into her throat; retching came on and she felt a shock internally, as if something had burst. This sensation she referred to the lower end of the sternum, somewhat to the right of the bone. Violent pain and a sense of suffocation came on, and a physician who was called in advised her immediate removal to hospital.

She was admitted shortly before three o'clock, after the symptoms had lasted about two hours. She had strength enough to walk with the aid of a couple of women from the visiting-room to ward No. 3, where she was located. When I had occasion to see her shortly after, she sat raised up in the bed and could not bear to lie down. She was thin, her countenance was anxious and slightly cyanotic, her neck was bent slightly backward, the front of her throat was much swollen, especially at each side of the windpipe, which was itself pushed considerably forward, being convex from above downwards. To the touch the tumour was elastic and was without crepitation. The attendant in the visiting-room stated, without inquiry on my part, that she was able distinctly to observe the increase of the tumour during the patient's short stay with her. The radial pulse was very small, particularly the right, and quick, the external jugular veins were swollen, the hands and feet were cool, and were slightly cyanotic. In the throat nothing morbid could be discovered. The examination of the thoracic organs exhibited nothing whatever abnormal. The heart was not enlarged, its sounds were pure. The lungs yielded everywhere, both anteriorly and posteriorly, a clear sound on percussion; when the patient drew a deep breath the anterior parts were well filled, the posterior and inferior parts were less perfectly expanded. Behind the sternum and beneath the left clavicle inspiration was remarkably rough. One of the inferior dorsal vertebræ was tender on pressure. Swallowing was quite impossible, as the attempt forthwith produced violent dyspnoea.

So far the symptoms were constant; but otherwise they exhibited a very peculiar intermission, while for some minutes the patient sat rather quietly in the bed, only rocking a little forwards and backwards, and complaining of pain in the epigastrium, in the back and in the right side of the chest, but so that both her voice, although it had rather a strange sound, and her breathing, were almost perfectly free, she drew herself the next moment violently together, distorted her face spasmodically, grasped at whatever was within her reach, roared for want of air and with pain, finally, got retching with vomiting of colourless, frothy mucus, and when a short cessation of the vomiting occurred, called for help that she might not be suffocated. Her consciousness continued perfect until she was shortly afterwards seized with convulsions, in which she died. On examination soon after death in the horizontal position we thought we could feel considerable distention in the upper part of the abdomen; the posterior wall of the œsophagus was also felt strongly pushed forward.

Imperfect as the history of the foregoing case was, for the information above detailed was in part obtained after the death of the patient, it was sufficient to establish satisfactorily that the woman had long suffered from some morbid state, connected with pain, in the lower part of the thorax, and that the dangerous symptoms which had recently occurred were due to rupture of the affected part. That the lesion was situated neither in the lungs nor in the heart, we thought might be decidedly inferred from the examination which had been made, and from its com-

pletely negative result, and we were therefore compelled to assume that the affection had its seat either in the œsophagus or in one of the larger bloodvessels. Rupture of the œsophagus is an exceedingly rare case, which has, however, sometimes been witnessed after previous disease of the organ, especially during the exertion of vomiting. The earlier symptoms might easily have had the œsophagus for their starting point, and if the tumour in the neck had exhibited any sign of containing air, this diagnosis would have had the greatest probability in its favour, as it is well known that no medium extends so rapidly in the connective tissue as air. But the absence of this one characteristic symptom destroyed the possibility of this assumption, and we were obliged to seek some other explanation. The idea of an aneurism of the descending aorta would then most naturally present itself; for although the preceding symptoms had not been very characteristic, they were not decidedly inconsistent with this diagnosis, bearing in mind the vague and obscure form, which this affection presents, on account of the deep situation of the vessel, before it has attained a considerable development. But I admit, that the intermission in the symptoms, and especially the swelling in the neck steadily increasing within a very short time, was a cause of no slight perplexity. It was, in fact, probable that the last-mentioned phenomenon might be due to extravasation of blood in the connective tissue, because, as we have just stated, we were obliged on account of the character of the swelling to exclude the assumption of air as the cause; but why should we connect a hæmorrhage in the cervical region with a rupture, which evidently took place deep in the thorax? On this point dissection alone could inform us.

The dissection was performed by Lector Reisz, the day after the death of the patient. Cadaveric rigidity was present. There was no emaciation. The neck was rather swollen, especially towards the sides. When the abdomen was opened, three or four small dark red, tolerably firm coagula were found lying free on the anterior and posterior surfaces of the omentum. In the omentum itself slight effusions of blood were met with, and several vessels were seen very highly congested. The spleen was tolerably large, pale, firm. The liver was natural, the gall bladder contained a large amount of dark bile. The kidneys were pale. The left lung was not adherent to the thorax, and its tissue was healthy. On the contrary, the right lung was attached by a couple of cord-like adhesions. The lung was highly congested; along its anterior margin, where the surface was of a strongly marked white colour, some dilatation of the air-cells was visible, in the lower lobe there was considerable serous infiltration (*vide infra*). In the pericardium a moderate quantity of clear serous fluid was found. The pericardium was smooth. The heart contained a small quantity of fluid blood, the valves were sound, as was the muscular structure.

The thoracic aorta presented throughout arterio-sclerotic changes with thickening of its walls and numerous elevated white fibrous spots of firm consistence. The walls of the carotids were in their normal condition, except that the inner coat was in a state of fatty degeneration. The arteria innominata was healthy, as were the jugular veins. Immediately above the diaphragm there was found on the aorta an aneurismatic dilatation of the size of a goose-egg, proceeding from the anterior circumference of the vessel. Into the aneurism led an opening rather larger than a four skilling piece,* with tolerably defined edges. The wall of the aneurism appeared in some places thickened, in others much attenuated; on the right half it was covered with a removable, thin layer of coagulable-like formation, and farthest to the right, adjoining the connective tissue in the posterior mediastinum, close to the inferior margin of the right lung, which had been adherent to the aneurism, was found a rupture of the tumour. This had produced extravasation of blood into the mediastinal connective tissue, and thence up the neck

* A coin of about the value of a penny.—TRANSLATOR.

to its deeper layer of connective tissue. While the extravasation of blood in the mediastinum itself formed only a narrow tract, it was found to a considerable extent in the connective tissue behind the gullet, where there were coagula of several ounces weight.

The *œsophagus* was in its upper half perfectly natural, in the lower part, which lay to the right of the tumour, it was somewhat compressed by the thickness of the surrounding extravasation of blood. In the *stomach* there were found, in vertical continuation of the axis of the *œsophagus*, a couple of ruptures of the mucous membrane of about three inches in length, without surrounding ecchymosis. These ruptures must be assumed to have proceeded from the fact, that the parts of its coat lying beneath the mucous membrane in the fundus and on the posterior surface of the stomach, were infiltrated with a large mass of coagulated blood. This, which therefore lay between the serous and the mucous membranes, was so considerable that the posterior wall of the stomach was rendered convex in its anterior aspect. A smaller coagulum was found between the layers of the lesser omentum. All the coagula were of a dark red colour. The extravasation of blood consequently extended from the base of the skull to down behind the stomach.

The abdominal aorta presented only in a slight degree the arterio-sclerotic changes. The brain and its arteries exhibited no abnormality. The vessels of the pia mater and arachnoid were slightly congested. The walls of the uterus were tolerably thick; the ovaries were shrunk; nevertheless the right ovary contained a tolerably large cyst.

The dissection explains the nature of what took place. An aneurism of the lower part of the thoracic aorta sprang from the anterior portion of the vessel, but in its development followed the direction of the latter to the right side. This accounts for the situation of the pain in opposition to the general statement as to its occurrence in the left side of the chest in accordance with the direction of the artery (Valleix, *Guide du médecin pr.*, t. iii., p. 370). The aneurism had not attained any great size, and the organ with which, from its situation, it might have been expected most readily to come into collision, was able, by its great mobility, to avoid the collision and its consequences. The deposition of coagulum was only inconsiderable and imperfect, along with which the bursting of the tumour in an early stage was favoured by the attenuation of its walls in many points, while the effort at vomiting was sufficient to determine the rupture. The rupture took place into the lax and abundant connective tissue between the two layers of pleura, and the blood was hence able, without meeting any essential obstruction, to work its way onward through the whole mediastinum, and in the neck to the retro-pharyngeal connective tissue, and to both sides along the carotids. The blood, too, sank downwards; it probably followed the *œsophagus* down to the posterior surface of the stomach, possibly also it accompanied the aorta through the diaphragm down to the celiac artery, and afterwards the branch of this, the *arteria coronaria ventriculi sinistra*, whose course from the epigastrium along the lesser curvature of the stomach, between the layers of the lesser omentum, coincides, as will be remembered, with the situation of the coagulum behind the stomach and in the omentum. Vidal's remark, already quoted, respecting the small size of the aneurism being favourable to its diffusion in the connective tissue, will here necessarily be brought to mind. The cause of this probably lies in the slight compression experienced by the meshes of the tissue, which latter were consequently not in a condition to oppose any obstacle to the effusion of blood. Nor will the corroboration of Zehetmayer's opinion as to the relation between the situation of the aneurism at the right side, and the course above described, escape us.

The previous examples of rupture of aneurisms into the mediastinal connective tissue quoted above, present only very slight similarity to the foregoing case. The mass of blood gushing out at once has been so considerable, and death has occurred so instantaneously, that time has not

been left for the dispersion of the effusion of blood over a great extent.* But from aneurisms of the abdominal aorta (Lebert, *l. c.*, p. 47) we know, on the contrary, the very great extent to which the effused blood may in many cases spread.

If we next put the question, whether the post-mortem examination has supplied us with a contribution towards the explanation of the peculiar intermission in the symptoms, the answer must be undecided. We are not disinclined to believe that the ordinary discharge of fresh masses of blood through the rupture was the cause of the constantly recurring exacerbations and finally of death; nor would we quite exclude the possibility that the pressure of the coagulum of blood on the stomach may have been active in producing the attacks, which, as will be remembered, constantly ended with retching and throwing up mucus; but while we propose these modes of explanation as possibilities we will add only, that remission is a common character of a great number of diseases, and especially of many chronic affections of the chest, which are attended with pain and dyspnea, so that it is properly only the acute course, the abrupt transition and the defined boundary between paroxysms and relaxation, which give our case its peculiar character.

Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.—MAY 3.

Dr. WALKER (V.P.) in the Chair.

A PAPER was read by Mr. HAYNES WALTON ON

DETACHMENT OF THE RETINA: ITS CAUSES AND TREATMENT.

Detachment of the retina from the choroid might result from an accident, such as a blow on the eyeball or about the orbit. But for the most part it cannot be traced to an injury. It was the physical effect of fluid effusions of various natures, chiefly, however, serous, or of firm solid deposits, or malignant disease. It was the class of cases produced only by the pouring out of serum, dropsy under the retina, that he should consider. This was of common occurrence, and one of the greatest mechanical changes that occurred in the eye, and yet, withal, was one without any external or objective symptoms. It was only by an ophthalmoscopic examination that the true nature of the case could be made out. These symptoms, as detailed by him, are undulating folds of the retina, or bulging of the retina in a tense form, the colour of the membrane varying from a light bluish or greyish tint to a dead white, which is characteristic of old detachment. The recognition of the retinal vessels removed doubt of the diagnosis; that the detachment might be partial, destroying sight to a limited degree, or general, totally annihilating vision; that the tendency of the affection was always to get worse, so that a worse class of cases could not occur. There was no opportunity for the natural reparative power. It was his conviction, however, that there was scope for treatment, and opportunity for success, and that this consisted in general and local measures; but the treatment should be commenced early, or little benefit could be expected. He deprecated the idea that a mere operative proceeding could be curative, dwelt on the pathology of the affection, and showed that it was the result of morbid action taking place within the eye of an inflammatory nature, and mostly of an asthenic form. The retina and the choroid being but slightly connected, there was but little or no resistance to extravasation, which quickly

* On the other hand we are not without examples of collections of pus in the mediastinum, proceeding from rupture of empyemas into this layer of connective tissue, forming dépôts in the neck, as occurred in our case. (Conf. L. Salomonsen's paper in the *Hospitals-tidende* for 1858.)

gravitated from one part to another. The separation of the retina after an accident he explained in the same way, first inflammation and then exudation between the retina and choroid. It was characteristic of the affection to proceed painlessly, and without any other symptom but that of impaired vision, the peculiarities of which were carefully pointed out. A remarkable case was given in illustration of his views. A patient was brought to him with detached retina in one eye of old standing, and inflammation of the retina of the other eyeball, producing among its effects haziness of the vitreous humour, so that the fundus of the eye could not be seen. After general treatment the vitreous humour cleared, the shreds and floating particles in it gradually disappearing, and then partial detachment of the retina was discovered. With all the morbid action in the eye there was not the slightest trace of disease in any of the external tissues. This was just the kind of case Mr. Walton said he was looking for. In the one eye conditions had been developed that left, as one at least of its effects, a separated retina; in the other was to be seen that intensity of internal action which, in all probability, was a parallel of what had taken place in the first, which in the end separated the retina. He operated on both eyes and evacuated the sub-retinal fluid. He found it necessary to operate a second time on the eye recently affected at the interval of a month, having up to that period still continued the general treatment, which consisted of small doses of mercury, with hyoscinium and a mixture of iodide of potassium with cinchona. The result was, in the eye with the acute disease the restoration of useful vision; in that which had been attacked two years ago no benefit ensued. Mr. Walton gave a detailed account of the method of operating, which was by puncturing the sclerotica and leaving the retina untouched, the fluid escaping between the sclerotica and conjunctiva. He assigned several reasons for preferring this to puncturing the retina. In the mass of the cases thus treated no benefit ensued, as the case was chronic; but in recent cases he had no doubt that the treatment had been successful in preserving useful vision.

Dr. C. DRYSDALE said that it appeared that the disease in question was caused by inflammation, and for this inflammation Mr. Walton advised treatment by mercury. Now, this was a question that belonged to the whole of medical science, and not alone to ophthalmic medicine, for if mercury would cure inflammation in the eye, of course it would do so elsewhere. But some of the most eminent physicians of the day—for example, Dr. Hughes Bennett, Dr. Walshe, and others—said that mercury was never of any service in any internal inflammation, such as pericarditis, peritonitis, pleurisy, &c. Then, descending to speculators. Hugh Carmichael of Dublin, Williams of Boston, Zachariah Laurence, Hughes Bennett, and other gentlemen, had published many cases of syphilitic and other forms of iritis which had got quite well without any mercury. He (Dr. Drysdale) had treated several cases of syphilitic iritis quite successfully without mercury. In fact, Mr. Acton had gone even so far as to say that it seemed as if iritis were sometimes caused in syphilitic patients by giving them mercury. Boeck was much averse to mercury in iritis, which he treated very simply, merely with a drop of atropine solution occasionally into the eye. He (Dr. D.) thought that the ophthalmic surgeons would soon be the only part of the profession who distinctly refused to surrender their belief in the absolute necessity of mercury in inflammations.

Mr. WALTON said that the necessity for the administration of mercury in inflammations of the eye was one of the facts he was most convinced of. It was not necessary to salivate, but gr. ii. of mercury and chalk should be given frequently. Turpentine was useless in iritis. The cases cited by Dr. Drysdale were, he must think, cases where the diagnosis had not been correctly made; iritis was an inflammation of the whole eye. Atropine did not act upon the retina when the inflammation was high, but only when it began to subside. With regard to authorities,

all those with whom he was accustomed to consult, as Mr. Bowman, Mr. Critchett, and Mr. Dixon, gave mercury in iritis.

Mr. BERKELEY HILL asked whether the cases referred to by Mr. Walton were simple separation of the choroid, or had he seen them in cases of syphilis? He was glad to hear Mr. Walton say that mercury was useful in iritis, as this always was his conviction.

Mr. WALTON said he could not answer the question.

Dr. STEWART pointed out that this was a question especially interesting in its medico-legal aspects.

Dr. COCK said that the question of the administration of mercury in inflammations depended upon opinion and diagnosis a great deal. As a general rule, he thought it not useful in inflammation of the pericardium of the lungs; but there were few physicians, he thought, who would not give it in pleurisy. Why did we give remedies at all? Because we wished for results.

A paper was read by Mr. BERKELEY HILL on

A CASE OF CHRONIC EMPYEMA, WITH FISTULOUS OPENINGS, TREATED BY REPEATED CUPPINGS, DRAINAGE, AND A REGULAR EVACUATION OF THE PUS.

A sailor, aged 29, of good natural constitution, was admitted into University College Hospital in August, 1864, with left pleurisy, with effusion, and great dyspnoea. He was tapped, and some pints of pus were discharged, and the hole at first closed. This relieved him a great deal; the chest collapsed, but in a few weeks the pus again accumulated; the pus oozed from the puncture; he was tapped at intervals varying from four weeks to three months, and on the last occasion an india-rubber drainage-tube was passed through the chest-walls and maintained a constant evacuation. He was, whilst wearing the tube, sent for a month to the sea-side, and returned so far convalescent as to be discharged. He worked as bargeman for two months, but the dyspnoea returned, and he re-entered the hospital again July 28, 1865. A drainage-tube was then inserted, but the fluid could only be partly cleared out by this method. Attempts were made to cleanse out the cavity, which now contained very offensive pus, and in September the tube was withdrawn, as it caused great irritation. Dr. Jenner requested Mr. Hill to endeavour to devise some method by which the pleural cavity could be evacuated as rapidly as the matter was formed. At this time a stream of foul stinking pus trickled from three sinuses in the fifth and sixth interspaces, gushing out when the patient coughed. He expectorated several ounces of pus daily. It was suggested that an attempt should be made to compress the chest-wall by an external apparatus, and Mr. Coxeter fitted up an apparatus with a spring, which pushed inwards the inner ribs; but the patient could not bear this. On the 30th of December a gum-elastic catheter was passed, and a few ounces of pus drawn off, and next day a straight pewter catheter was inserted for three and a half inches, through which thirty-four ounces of putrid matter exuded. This catheter was left in four hours, and relieved him greatly. For the next three days 31 ounces, 21 ounces, and 21 ounces were withdrawn; on the 6th, 16 ounces were withdrawn, quite inodorous. The appetite was excellent, and the temperature fell from 100° to the normal heat. Until the 11th the tube, passed daily, drew off 12 to 16 ounces of pus. He was then able to rise; his chest measuring 16½ inches on the diseased side, and 18½ on the sound side, having been 19½ on the diseased side before vacating the pus. The percussive note on the diseased side was only partially resonant in the infra-clavicular regions, amphoric at the nipple. Finding it impossible to prevent air entering while the instrument was drawing off the fluid, a valve was constructed, which when submerged in water completely prevented the return either of air or pus into the thorax. The amphoric resonance was then removed.

January 15th: The daily evacuation was 6-7 ounces.

17th: He had gained seven pounds in weight; chest, right side, 18½; left, 16, on January 22nd.

February 4th: After evacuating some pus the left side measured 17 inches. The heart's apex was now $1\frac{1}{2}$ inches left of the sternum, and respiration was heard distinctly over the whole of the left lung.

18th: The patient declared himself to be as well as he ever was in his life, and asked to be discharged. He went to Eastbourne for three weeks, and returned stout and well, still drawing off an ounce or so of pus every morning. Discharged with instructions to draw off the fluid daily.

April 29th: He called at the hospital to say that he was in excellent health, still drawing off \bar{z} i. daily. In purulent collection in the pleura, then, the man's condition of cure consisted, Mr. Hill said, in the complete and regular evacuation of the pus contained.

Several authors also had shown that little permanent benefit could be expected, unless the opening were made permanent. The case of Dr. Wendelstadt was referred to, who, after an attack of empyema, for thirteen years withdrew daily by means of a catheter a small quantity of pus, and remained in excellent health. Iodine injections had been advised in like cases; but in this case the plan of letting well alone had been adopted. It is impossible to prevent air getting into the chest; but if in small quantities, it only does harm if the fluid be allowed to collect. The readiness with which expansion began in the lung showed that permanent collapse and consolidation took place very slowly, as the man was nearly two years with more or less fluid in his chest and the left lung compressed against his spine, yet it soon began to expand and had regained some of its natural volume when the man left hospital. He concluded, then, that when paracentesis was performed in empyema, means should be taken to drain the cavity continuously, and then the fluid should be drawn off as it was formed. Caustic injections might be employed.

Mr. HAYNES WALTON said that in several cases where he had performed paracentesis thoracis for Dr. Hamilton Roe, he had made use of an apparatus resembling a stomach-pump inverted. This completely prevented the entrance of air into the pleural cavity. He had made use of the same apparatus in evacuating a lumbar abscess, without, however, succeeding so well, from some cause he could not account for.

Dr. DRYSDALE said it was clear, from the happy termination of Mr. Hill's case, that if empyema were tapped, the fluid should be daily evacuated. Much could be said for and against the practice of tapping the chest. In the first place, the great majority of cases of empyema proved fatal when they were tapped; but, then, if not tapped, the patient's life was often not worth having, and only a long struggle. M. Trousseau's work on "Clinical Medicine" had produced quite a revival of the operation of thoracentesis, both in empyema and in pleurisy with serous effusion; indeed, some persons seemed always to perform tapping in pleurisy with effusion. He believed that in some cases of large effusion, especially if double, life might be saved or prolonged by the operation. Not long ago he had counselled the operation in the case of a gentleman with large pleuritic effusion into the right pleural cavity threatening imminent death. The suggestion was not adopted, the patient recovered; but the lung was so much affected that he gradually declined in health, and died of phthisis after considerable suffering. Most cases, however, of pleurisy with effusion did well, if let alone, and it was only the exceptional cases that led to such bad results. As a general rule, then, he thought thoracentesis should not be employed in empyema, and only in pleuritic effusion when very large and threatening dissolution, or when the strength was much reduced by the loss of the lung's action. As to keeping out the air, this was indeed a difficult matter, as far as he had seen.

Dr. COCK said that effusion might take place so rapidly as to threaten death by suffocation, in which case thoracentesis was indicated. Effusions, however, in the last stages of phthisis should not, however, be meddled with in

his opinion. In cases of chronic effusion, too, in the chest, it would be well to avoid operation. The chief indication for operation he conceived to lie in the presence of effusion in both lungs and the danger of rapid dissolution.

Dr. MORTON said that an American physician had practised the operation of paracentesis thoracis to a great extent. Dr. Fuller, however, had published some cases which seemed to be unfavourable to the practice. Beyond a certain point there was difficulty in making the pus flow. He thought the operation ought not to be performed unless we feared imminent death unless the fluid were evacuated.

Mr. BERKELEY HILL was glad to hear that Mr. Walton had succeeded so well with the apparatus he had used for preventing the entering of air into the chest. As to the operation itself, it was a most simple one, and exempt from any danger in itself. The entrance of the air had always been the occurrence most dreaded. Patients with large effusion died of syncope in most cases, not from suffocation, he believed.

ROYAL DUBLIN SOCIETY.

EVENING SCIENTIFIC MEETING, MAY 28.

ON LABORERS' DWELLINGS:

SUCCESSES AND FAILURES OF EFFORTS TO IMPROVE THEM BY MEANS OF INSPECTION, LOANS, AND PUBLIC COMPANIES; AND THE EXPEDIENCY OF EXTENDING TO IRELAND THE COMPULSORY PRINCIPLE IN THEIR ERECTION AND MAINTENANCE.

By E. D. MAPOTHER, M.D.,

PROFESSOR OF HYGIENE, ROYAL COLLEGE OF SURGEONS, IRELAND.

SINCE I placed this paper on the Society's list many unexpected demands have been made on my time, and in this way I account for many imperfections which I fear you will perceive in its arrangements and fulness. The subject of the dwellings of the labouring classes presents itself in so many aspects, and there are so many professional gentlemen and landed proprietors present whom I am anxious to engage in the discussion, it will be best brought before you by my making my own observations as brief as possible.

The dwellings of the poor in cities, towns, and rural districts in Ireland, are ill-constructed, dilapidated, overcrowded, and unwholesome. Let me attempt the description of one or two in each of these situations—Gill Square is a blind court opening by a narrow archway, under one of the houses in Cole Alley, Meath-street, in this city. In it there are nine three-story houses, built on three of the sides of a square of about fifty feet; the roofs are broken, the walls present a most unsafe and tumbledown aspect, the windows are boarded up for more than half their space. Every room is to the utmost overcrowded with beings whose dirty, ill-clad, and spiritless aspects it is saddening to behold. There is but one yard for all, and in this, till last year, there was a hovel about ten feet high and eight square, in which three adults were huddled. Here, however, time has wrought improvement, for there now remains but a heap of rubbish. If I had time, or if it were my province to depict the moral features of the denizens, they would appear of even a more degraded character than the buildings, and of no place could the words of Kingsley be more truly descriptive:—

"I turned into an alley 'neath the wall—
And stepped from earth to hell. The light of heaven,
The common air was narrow, gross and dun—
The tiles did drop from the eaves; the unhung doors
Tottered o'er inky pools, where reeked and curdled,
The offal of a life; the gaunt-haunched swine
Growled at their christened playmates o'er the scraps.
Shrill mothers cursed; wan children wailed; sharp coughs
Rang thro' the crazy chambers; hungry eyes
Glared dumb reproach."

In a neighbouring house in Cole Alley some years ago, twenty people were found lying in one room, of whom five

were ill with fever, and Mr. N. Robinson has ascertained that in the 171 rooms of this alley there exists an average of over five persons.

56, Bow-lane, West, I have described in a recent report to the corporation as follows:—Hall and stairs covered with three inches of crusted filth; first flight so ricketty as to be unsafe; second without a bannister; floor of second landing broken into two holes about a square foot each; dangerous to life and limb; ceilings of both top floors broken and let in rain; no lower sash in window of back room, so that it had to be covered with a petticoat nailed over it; such state would produce colds and rheumatism; filthy privy, and back yard without a sewer—prolific causes of diarrhoea.

Poverty of the owners is not the cause of the dilapidation of these abodes, for the persons who set them, like many of their class, have raised themselves to comparative affluence by profits thus gained from the poor.

There is much of this kind of property owned by respectable persons who never enter it, but leave it to be managed by the "deputy" or agent who is not usually of an improving spirit. In proportion to space such tenement houses are highly rented, far more so than the gentleman's house.

In Cork things are no better, as we learn from recent reports of the Sanitary Committee. "The overcrowding of the wretched tenements in which they live, each house containing several families, ranging in the aggregate, in some instances, from thirty to sixty human beings, male and female, in each house, for which large rents are exacted by the landlords, who will not spend one penny in the cleansing or improvement of their houses, unless coerced by force of the law to do so. Your committee have learned that a practice prevails amongst poor families occupying rooms in these houses to underlet a portion of their rooms to nightly lodgers—an evil which it appears to your committee might be met by the enforcement of the Lodging House Act." Such were the worst parts of London, undrained, dilapidated, and thinned by pestilence every few years before the fire of 1666, which therefore cannot be regarded from every point of view as a calamity.

The labourers' cottages in such small towns as Chapelizod, Navan, Carrack-on-Suir, or Ennis, are usually built in lanes, and are often placed back to back, excluding all chance of thorough airing, or the provision of sanitary accommodation; they consist of a single room or a living room and a sleeping place of about twelve feet square and eight feet high, which offers for the breathing of the five inmates (the average) and the vagrant, who is almost invariably accommodated with a night's lodging, about 192 feet of space, 1000 being the average in public institutions. This would not be so hurtful if there were any means of renewing the air within it, but from the absence of a chimney in the sleeping room, which is usual, the small size and immovable state of the windows, no ventilation occurs. In such an overcrowded state there can be no decent separation of the sexes. When a death from contagious disease occurs in such an abode, the retention of the body within it is fraught with fearful evils, and since the abolition of the Vestry Act there were no funds for interment, and if the relatives were unable to provide them they had to beg the amount from the neighbours. Sir Hervey Bruce has, however, obtained an Act this session which empowers poor-law guardians to bear the expenses of interment.

Neither in such a room can ablution of the whole body be accomplished, and I have frequently found persons (especially females) suffering from skin diseases and other maladies, who for many years had never washed any part of their bodies but the face, neck, and hands.

Evictions and the demolition of cabins in the rural districts have driven agricultural labourers into the small towns, and as new abodes in the place of those removed would be subject to taxation, they have not been erected. Besides the fearful overcrowding thus induced, the labourers have to expend their strength in walking long

distances to their work. The remedy is that which followed in England last session, upon a masterly demonstration of its necessity by Dr. Hunter, of the Medical Department of the Privy Council—namely, union rating, for which a Bill has been introduced by the Members for Dungarvan and Limerick.

The mud hovel of the Southern and Western peasant is too well known by the sketches of English tourists to need any description here. Planted anywhere, regardless of situation or soil, the low walls, the black, half-rotten thatch, the want of any proper flue or of windows (for the hole filled with an immovable and partly glazed sash cannot be so regarded), the clay floor, which becomes soaked with the pigs' food or more dangerous filth, and the adjacent manure heap, are all highly promotive of disease. From the want of a back door, thorough airing can never be effected.

The admission of domestic animals, the pig especially, has done much to propagate measles and other parasitic diseases, which are afterwards injurious to man when their flesh is used.

Mr. Godwin of the *Builder*, has often quoted the description of the way in which the inmates are disposed, as observed by a medical friend of mine:—"Generally the pigs dwell beneath the beds, the human tenants in them, and the poultry over head; the people can enjoy the prospect of bacon and chickens, which, however, they never taste."

If there be an inner room it is close and stifling, and so ill-lit that when the doctor pays his visit in the daytime a candle is required to permit him to see his patient.

There are in Ireland, according to the last census, 89,374 mud or sod hovels of one room only, and 489,668 mud houses with more than one room, giving an increase in Connaught of 5168 of the latter class since 1841. The average number of persons occupying each of these dwellings is in towns 4·53 and in the rural districts 5·24.

Now, the remedy for this deplorable state does not lie in the labourer's hands, however great his willingness to pay for better accommodation, but with the landlord when he recognizes the duties which appertain to his property. Many diseases are produced, promoted, or rendered more fatal among the poor, and if contagious, spread to the rich by such conditions as I have sketched.

(a.) Fever.—The man who is depressed by the want of fresh air is more liable to catch contagious disease, and in an overcrowded ill-aired room it must spread to others when one is stricken down. During the epidemic of the first quarter of this century the practice when fever seized a cottager was to build off the part of the room in which he lay, and to introduce through the window any food or medicine he required. A more disastrous consequence of the ignorance among the people of the laws of health perhaps never occurred. One and a half millions of cases were reported in the epidemic of 1818. The fever rate of Irish towns is constantly and fearfully higher than that of English towns, owing to defective house accommodation and the reception of vagrants who spread the contagion.

(b.) Diarrhoea must always prevail, and typhoid fever and cholera when introduced must spread, if there be no efficient means for the removal of refuse, and if it be allowed to soak around the dwellings and poison the wells and the atmosphere. Gastric fever is a usual pest of the cottager's children and is produced in the same way.

(c.) Convulsions carry off so many infants in Irish towns as to greatly raise their mortality, and this disease is the effect of impure air acting on the susceptible nervous system of infancy.

(d.) Consumption and other forms of scrofula are, without doubt, promoted by want of pure fresh air, and are becoming lamentably fatal in many of our northern towns.

(e.) Accidental deaths occur likewise by overcrowding; thus during the last ten years, in Liverpool, 828 deaths of infants have been caused by overlying.

The other physical and the moral evils which result from

the wretched condition of the habitations of our poor, I shall not now touch on, but they are subjects preëminently important for the philanthropist and the statesman. The evils which neglected dwellings impress on our countrymen are carried with them when they emigrate to British and American cities, in which the term "Irish" applied to a neighbourhood is the synonym for "wretched and filthy;" and galling to our national pride, as the expression is, no candid man can deny that there is some truth in it. It becomes the duty of every man to lend his aid in removing the causes which lead to such universally recognized degradation.

The means which legislation has heretofore provided for the improvement of the dwellings of the humbler classes have been inspection and the advancement of Government loans.

Inspection in towns in Ireland is only allowed in nightly lodging-houses duly registered, and only when the population exceeds 3,000, and the town has been placed under Commissioners by the adoption of the Improvement Act of 1854. In England exemption is only granted for those below 200, and in Scotland below 700. Overcrowding is thus irrepressible in hundreds of towns which fall below that population, and in Parsonstown, Arklow, Kilrush, Portlaoigh, Roscrea, Macroom, and Boyle, which, although above it, because they have not adopted any Improvement Act. As an example of a town which is overcrowded by the reception of vagrants at night, I may mention one very near us—namely, Swords. As few of the towns which have adopted the Act of 1854 employ any inspector, it follows that nightly lodging-houses are unregulated in Ireland, except in a few of the larger cities.

Power to inspect the tenemented dwellings of the poor in the same way as common lodging-houses has been advocated by the ablest writers, and first and most forcibly by the Rev. Charles Kingsley, but Dublin is the only city in these kingdoms to which it has been granted.

Such powers were conferred last year under the Dublin Improvement Act, and are now anxiously sought for by London and other English cities, through their health officers and representatives. Under the Improvement Act of 1847, bye-laws were already in force regarding the following matters over nightly lodging-houses:—Registration; inspection; number of lodgers; separation of male and female lodgers; airing and cleansing; notice of infectious disease and disinfection; water supply and domestic accommodation; exclusion of swine and other animals; and the keeping of a copy of the regulations in each room.

Ninety-five such houses were registered and regularly inspected, and one single fact will prove with what advantage; an average of one case of fever yearly occurred in the whole of them, whereas nearly every tenement house produced a case.

Such considerations induced the Corporation to seek power over tenements set weekly at rents under 3s., and the Lord Lieutenant sanctioned bye-laws respecting the condition of roof, walls, windows, house-drain, and other sanitary requisites, and imposing penalties on the owner for neglect in these respects, and on the occupier for any offence in injuring or abusing such accommodations. The owners of some of these houses, which number about 9000 of the entire houses in the city, at once organized themselves into a body with the grandiloquent and scarcely intelligible title of "The Antipolitical Ratepayers Protective Association," whose object was to protect themselves from the outlay necessary to render the houses fit for human habitation. By representations that the dwellings of the poor were in excellent order, that the Corporation were about to apply the bye-laws for the regulation of furnished nightly lodging-houses to tenement dwellings, by memorializing that body, and threatening many of its members with opposition at the next election, and by appeals to the police magistrates, they have as yet to a certain degree impeded us, notwithstanding the deplorable state of houses, such as I have exemplified, in Gill-

square and Bow-lane. On Wednesday last, however (the question having been argued by most eminent counsel), the magistrates decided in favour of the Sanitary Committee, and fined the Secretary of the Tenement Owners Society for not having registered a house kept by him. So determined are their efforts to oppose us in carrying out the sanitary bye-laws that they have lodged an appeal to the Queen's Bench. They complain that the term "common lodging-house" is an opprobrious epithet to apply to houses set in tenements. The difficulties of keeping a registry of 9000 houses with changing owners are so great, that I trust some future act may declare registration unnecessary for "tenement houses," as distinguished from "common lodging houses," in which such a system is required.

The bye-laws came into action on the 15th day of September, and the sanitary sergeants forthwith proceeded to enforce them. Those neighbourhoods which from experience were known to be most filthy and unhealthy were first visited, a copy of the bye-laws was posted in each house, and a familiar explanation of their provisions was given to each occupier of a tenement in it. In many instances the improvements which the sanitary sergeants suggested were carried out; in others they were resisted, and the owners were accordingly summoned. The police magistrates, however, adjudged that registration of each of these houses as a public lodging-house was necessary before conviction for any sanitary deficiency could be obtained. The registration of these houses, which number about 9000, has caused considerable delay, and occupied the time of the staff for the first four months. I should mention that the visits of the officers were always most gratefully received by the poor tenants, and the allegation of the house-owners as to their being intrusions on their privacy and liberty were quite unfounded. During the eight months the act has been in operation 3974 houses have been visited, 92,707 sanitary defects discovered, and the larger proportion of them corrected.

It is most gratifying to know that in the amended sanitary legislation which the Government have promised this session the power of regulating tenement houses will be extended to all other Irish towns as well as the power to prevent overcrowding as at present possessed by English acts. The act for the inspection and regulation of lodging-houses in England, obtained by Lord Shaftesbury, was followed in 1851 by the act to encourage the establishment of lodging-houses for the labouring classes, which provided that in towns of 10,000 inhabitants the local authority might borrow money from the Loan Commissioners for the purpose of building wholesome dwellings for the labouring classes. The desire to improve the condition of the operative classes in English towns is so general that I was surprised and disappointed to find that the act has been only taken advantage of in one instance during the fifteen years it has existed. In that instance (Huddersfield) the success has been remarkable. In 1864 it provided for 40,928 nightly inmates at a profit of £90 14s. 1d., and in thirty years the establishment will be the property of the Town Council, principal and interest having been paid. This act being thus a dead letter, the "Labouring Classes Dwellings Act" (just passed through the efforts of Mr. Childers) extends the granting of loans for this purpose to public companies and to individuals, who can offer fit security at 4 per cent., and repayable over forty years. A similar bill for Ireland, introduced by Mr. Childers and the Attorney-General, has obtained a third reading, and it possesses a valuable additional clause, providing that buildings, ruinous or dilapidated because of defect of title, may be sold in the Landed Estates Court.

Such acts are perfect as permissive enactments, but for reasons I will just now mention I fear that, as in the case of the Act of 1851, the supineness of municipal bodies and landed proprietors will to a great extent render them nugatory.

In 1855 Sir W. Somerville and Mr. G. A. Hamilton ob-

tained an act which much facilitated the improvement of labourers' dwellings by granting the power to the landlord to recover possession under the Summary Jurisdiction Act of any tenement or cottage of a labourer, which, having been previously provided with every sanitary appliance had fallen into dilapidation. The same member, after some unsuccessful efforts, procured the enactment of the statute sanctioning the granting of loans on most favourable terms to landed proprietors for the erection of agricultural labourers' dwellings, and the Commissioners of Public Works, to whom the management of the statute was entrusted, published regulations and specifications for the work. They also offered plans for the buildings, to which, however, the proprietors were not bound to adhere. No loan was to be granted for repair of old houses, the sum was to range between £200 and £1000 for any one person, and no larger sum than £60 was granted for each cottage, one-fourth that sum being added by the landlord, who was also obliged to provide for each dwelling a properly-drained privy, ashpit with puddled walls, and yard. Most glowing anticipations were entertained as to its effects in improving the wretched habitations of our peasantry, but I regret to say that they have been realized to a very inconsiderable extent. More than half the time of the act has run (for it is to cease in 1870), yet, according to the last report of the Commissioners (1865) but nine loans, amounting to £4,900, has been sanctioned for dwellings completed. If £60, the usual loan, be divided into this, it may be supposed that about 80 cottages have been erected. Considering that there were in 1861 at least 200,000 cottages requiring to be rebuilt, and that the overcrowded state of labourers' dwellings is so notorious, it is much to be deplored that landed proprietors have not taken advantage of this admirable enactment in a degree at all adequate to the wants of their tenants. From the same report it appears that eighteen loans, amounting to £6,290 were sanctioned, but not proceeded with, and that sixteen, amounting to £8,800, had been about half completed.

A stroll over the Hill of Howth will practically convince any one of the advantages of the act; in few parts of Connaught could more wretched hovels be discovered than existed here some years ago. Now, their places are taken by several neat and wholesome dwellings for the labourers, which are set at highly remunerative rents. The cottages are kept in excellent order, and the same gratifying report may be made of many others of those erected under the act.

Many counties, for example, Galway, Mayo, Leitrim, and Roscommon, or nine-tenths of the western province, which most sadly require improved dwellings, have never had a loan granted, no application, I presume, having been made by the owners of the soil.

In the working of the Act there is a serious difficulty, which, I trust, may be removed by future legislation. I can best explain it by an example. A landed proprietor in the south having a large tract of unimproved land, let it to good tenants in small holdings, and granted long leases. His property has been vastly improved and his tenants aided in the safest way. Instead of being rewarded, however, by the benefits of this act, he is ineligible from receiving loans under it by the fact of having given leases, and further, the tenants are incapacitated by the smallness of their holdings from seeking the responsibility of a loan of £200, the least to be advanced under the Commissioners regulations. Scotland has enjoyed a similar act, which has been largely taken advantage of by land owners there. Until Mr. Childer's Act of this Session landed proprietors in England had not similar privileges.

Throughout this country there are a few large landed proprietors who have interested themselves in the improvement of their labourers' dwellings before this Act had been passed for Ireland, and the pretty and healthful cottages at Loughcrew, Clermont-park, Enniskerry, and Santry, occur to me in illustration. The Royal Agricultural Society has aided the good work by offering several gold and silver medals for the erection of the greatest number

of newly-built labourers' cottages, or of improved cottages, in each province, or county, or district of its local branches. There is also the Leinster challenge cup for the person who, during the year, shall have erected the greatest number of improved labourers' cottages in any part of Ireland. Stimulated by these rewards some hundreds of cottages have been built and put in competition, as appears from the yearly reports of the Society.

With regard to the plans on which these dwellings should be constructed, I will not, of course, attempt to enter into details, but I exhibit these models from the Agricultural Museum of our Society representing some which have been erected, and these elevations and plans for a pair of labourers cottages have been drawn by my brother, Mr. Dillon Mapother, C.E., of Louisville, U.S. They are adaptable for a small or large family by extension of the partitions, and as all ornament is omitted, the expense would range between £60 and £75 each, every sanitary requisite being provided.

These other plans are being carried out on the premises of Messrs. Walpole and Webb, and at Bray under the direction of Mr. C. Geoghegan, architect, and are intended to accommodate four families in each building.

There are also on the table several valuable plans which have been kindly lent to me by Mr. Barry, Commissioner of Fisheries, who has laboured longer and more energetically on the subject than any one with whom I am acquainted. A friend has informed me that cottages are made for a very small sum in France, by moulding in wooden shapes the scrapings from the streets, but I fear that, like the mud cabins, they would not allow permeation of air. In London and other great cities the greatest advantages with respect to health, prosperity, and morality, have followed the erection of improved lodging-houses and family dwellings for the working classes. They have been in many instances highly remunerative, even up to 14 per cent. on the outlay. In other cases where the noble benevolence of Mr. Peabody and others justified a greater expenditure than could be recouped in rents, the return has been as low as 3 per cent. Perhaps the Cromwell, Tower, Cobden, and Stanley buildings of the Industrial Tenement Company, which accommodate 200 families on the open staircase principle, may be taken as a medium. The profit from these has ranged from $6\frac{1}{2}$ to 9 per cent.

Much has been done in London towards providing fit dwellings for the humbler classes; but so great is the aggregation of people reared in the country, and so vast the demolition by railway and other works, that overcrowding is most excessive and typhus is yearly increasing. Mr. Thomas Hughes was, therefore, justified in moving this week on Committee on Railway Clauses Bill that compensation should be given to tenement holders where more than fourteen houses in a parish have been removed, and that the company should provide wholesome dwellings in place of those removed, and should have compulsory power of taking sites for the purpose. He is favourable to the system of providing dwellings out of the city, the railways to provide cheap trains. This principle has been largely adopted in France, and, as far as it has been tried in London, it has succeeded. In Irish cities the condensation of population is not so great as to need this. In that most comprehensive and delightfully written book, "The Homes of the Working Classes," by Mr. Hall, there are most interesting descriptions of Saltaire, Akroydon, the familistery at Guise, and the cités Ouvrières of Mulhouse, where most admirable villages have been constructed for manufacturers workmen.

In Edinburgh, 16 buildings accommodating 847 families have been erected, and they have all been peculiarly successful.

In this city something in this direction is at last about to be done; the Industrial Tenements Company (limited) has just been established with a most influential directory, who have entered into the movement in a spirit of commercial enterprise, which alone can make the project remunerative, and on a scale adequate to the wants of our

labouring population. From their prospectus I make the following extracts:—

"This Company has been formed for the purpose of remedying an evil that exists in the city of Dublin, and of providing for the poor and labouring classes tenements in every respect superior to their present unhealthy and miserable dwellings.

"The Company propose to acquire, by purchase or lease in the city of Dublin, old but substantial houses, which, owing to the decline of the locality in which they stand, can now be purchased or obtained on lease for long terms of years on advantageous terms, and by an economic outlay fit up these houses in tenements, providing each set with all sanitary requirements, thereby ensuring to the labouring man the elements of health, cleanliness, and comfort.

"The Company also contemplate erecting improved dwellings on the principle adopted with such signal success in London, Edinburgh, and all the leading cities of Europe.

"There are at present 9000 houses let in tenements throughout the city of Dublin, in very few of which (if any) is the sanitary condition of the occupant cared for, and in nearly all of which the common decencies of life are lost sight of, whilst in most cases the rents paid for these tenements are exorbitant for the accommodation afforded.

"From the working of the improved dwelling companies in London, it has been found that the artisan and labouring classes are most punctual in the payment of their rents, and that every vacant tenement is eagerly sought after.

"The Company have ascertained that there are most suitable lots of houses in the city of Dublin that can be obtained on advantageous terms.

"The preliminary expenses are confined to the actual outlay incidental to the formation of the Company, no promotion money or any payment of a like nature being sanctioned by the articles of Association.

"The promoters have been induced to divide the capital into £10 shares, in the hope of inviting the artisan to invest his savings in the undertaking, and thus give him an additional incentive to promote the prosperity of the Company."

The financial success of improved dwellings erected in this city by Mr. Thomas Vance, Dr. Evory Kennedy, and Mr. Lindsay, has been remarkable, and there are always many eager applicants for tenements when vacant, which facts augur well for the success of the company.

The most important measure in regard to the subject ever introduced is that which Messrs. McCullagh Torrens, Locke, and Kinnaird brought in on the 20th of February. It is entitled, "a Bill to Provide better Dwellings for Artisans and Labourers," and applies to any borough or district in England to which the Public Health Act has been granted, or any place in the metropolis governed by a vestry. It provides that upon application of twenty rate-payers of any town, parish, or district, or by resolution of the local authority whenever the death-rate for three successive years shall have been over 3 in the 100, the Home Secretary shall send an inspecting architect to inquire into the sanitary state of any street, the number of persons living in it, the space and accommodation afforded, and the steps necessary to obtain sufficient healthful houses for the inhabitants. His report shall be laid before the local authority, published within fourteen days, and unless within a month the local authority shall prove to the Home Secretary that the improvements are not needed, he shall order them to be executed within a reasonable time. The dwellings to be constructed in lieu of those condemned shall be built with every sanitary accommodation, and so as to afford 350 cubic feet of space for every occupant. For these buildings the Loan Commissioners may advance money on the security of the rates at three and a half per cent., to be repaid within thirty years by equal yearly instalments. The local authority is to have power to take land or sites for buildings, giving compensation to the owners, and is to manage the improved dwellings. From this latter responsibility they will be relieved after three years by a clause which Mr. Torrens has undertaken to insert. I think some clause empowering the authorities in very condensed populations to convert the sites of the condemned houses into open spaces is very desirable, the

displaced inmates to be provided for in suburban districts connected with a railway at penny fares.

The compulsory principle on the occurrence of a fearful death-rate is the peculiar and valuable feature of this Bill, and without it no considerable amount of improvement will be achieved in the dwellings of the industrial classes. This is conclusively shown by the facts, I have before mentioned—namely, that the Loan Act in England has in fifteen years procured the building of one house, and the Irish Loan Act has in six years been instrumental in the building of some eighty cottages. As the former failure and the want of sanitary improvements in Irish towns is attributable to the apathy and mistaken parsimony of local authorities, I rejoice that in the "Labouring Classes Dwellings Ireland Act," it is provided that loans may be also granted to public companies and estates individuals. So ill understood and so uncared for is the condition of the humbler classes in towns, that when that mild and permissive measure was passing through committee it was characterized as "a monstrous bill" by an Irish county member. Mr. Torrens' bill has been referred to an admirably chosen Select Committee who have not as yet reported. Meanwhile thirty-seven bodies have petitioned in favour of it, and two against. The Dublin Corporation and the Irish Medical Association, have petitioned for its extension to Ireland.

A joint Committee of the Society of Arts and the Social Science Association has prepared a bill entitled, "The Improvement of Dwellings for Labourers" and Artisans Act, 1866," which Mr. Charles Buxton is to introduce. It gives compulsory powers to Corporations to take land and build dwellings, the Home Secretary sanctioning the steps and the advance of loans for the purpose. It contains the usual selfish clause, "This Act shall not extend to Scotland or Ireland." It seems to me but to complicate attempts at legislation, for Mr. Torrens' Bill better provides for the same objects.

The metropolis, Liverpool, Birmingham, and other large English towns possess local Acts for the complete regulation of their buildings, and the smaller towns are similarly provided for under the bye-laws of the Local Government Act, 1858. Under these powers no house can be built unless its walls be of certain thickness proportional to height, unless sufficient space be allotted for a yard, unless the lower storey be efficiently drained, unless the roofs and chimneys be properly and safely constructed, and unless every habitable room be of a certain height. These provisions are placed under the supervision of the District Surveyor. Such a Bill for Dublin, on a very comprehensive scale, was prepared in 1863 with the aid of our Borough Engineer, but was never introduced. That it is required, a single example out of hundreds of ill-constructed, unimprovable buildings will show.

In Stephen's-place, which leads from Upper to Lower Mount-street, the houses are built back to back, without any thorough airing, yard, or privy. Filth must be therefore cast on the roadway. The clergymen and inhabitants of that aristocratic neighbourhood have justly complained, but the remedy is not easy. The placing of a water-closet, which the poor would soon disarrange is not safe in an unaired house, and as the houses are owned by different persons, the Corporation can scarcely require that one shall be converted into a privy for the use of the occupiers of all the others, as we have done where one person owns several cottages. In other houses without yards or accommodation, filth has been accumulated to a vast extent in the cellars or back kitchen.

The Local Government Act is most useful with regard to new buildings, but does not interfere with those already erected, no matter how unwholesome, so that this addition would be desirable if the Act is extended to Ireland.

In Glasgow many of the courts and houses are very ill constructed, and so overcrowded are they as to allow but the average of three square yards to each person. A bill, however, for improvement, with compulsory power, has passed unopposed through Committee, by which the rate-

payers consent to tax themselves at 6d. in the £1 for five years, and 3d. for the ensuing ten years. It is provided that the improvements shall not go on so fast as to render houseless the present occupants, but that reconstruction shall go on *pari passu* with demolition. In Liverpool, under the Sanitary Amendment Act, 226 houses in 189 courts were removed or altered during last year. As many other great sanitary improvements have been achieved, the only circumstances which seem to account for the still excessive death-rate of that city is the extreme condensation of its population. There should be also some efficient controlling authority for the laying out of towns and streets. While the rectangular form, with due regard to meteorological circumstances, so common in American cities, is most healthful, our towns, as will be seen from these index maps, consist of angular streets of such devious courses as to appear rather the result of chance than design, and blind courts, which are most insalubrious. As yet scarcely any town in Ireland can boast of a wide street planted with trees.

In France the dwellings of the operative classes, as well as all other sanitary matters, are directed by a special branch of the state, named "Commission de Salubrité Publique," and a most effective machinery is organized to see that all houses are built on proper plans, and are preserved in good order.

Some very conclusive arguments have been put forward that Public Health Committees of the Privy Councils of these kingdoms should be charged with the control of town authorities, as the Poor-law Boards are with that of the local guardians. As precautions are often neglected during freedom from epidemics, inspection is then needed to a greater degree than even they are among us. But in many places it is only when the selfish fear of contagion creates a panic, or when the pestilence has already invaded, that active measures are taken, and in the latter case their usefulness is very doubtful.

I will sum up in a very few words what I hope for as necessary to improve the dwellings of the poor, and thereby raise immensely the standard of public health:—

1st. The constitution of a central controlling authority for local government and sanitary improvement.

2nd. The enactment of a comprehensive building code; the passing of local acts being expensive is often avoided.

3rd. That our sanitary laws should be compulsory in cases of flagrant neglect; the permission to act is now very generally construed as permission not to act.

4th. A generally diffused desire on the part of employers and land owners to provide for the healthful wants of their dependents, and this will grow according as our nation prospers, and according as the masses are educated in the knowledge of the laws which regulate the well-being of their own bodies.

That the subject I have thus so imperfectly submitted to you is closely connected with our prosperity, cannot be more forcibly expressed than in the words of the Devon Commissioners, which are painted in large letters over the entrance of our Agricultural Museum: "While the dwellings of the general body of the people are surrounded by the elements of disease, and are damp, cold, dirty, and comfortless within, so long will the country be destitute of even the semblance of general prosperity."

An interesting discussion followed, in which the Chairman, Dr. E. Kennedy, Mr. Daly of the Dublin Building Society, Mr. Jephson, Mr. Thomas Begg of London (who has been the ablest advocate of the subject in England), Mr. Dillon Mapother, and Dr. Steele took part.

THE Medico-Chirurgical Society of Edinburgh held its ninth meeting of this its forty-fifth Session in its Hall, 117, George-street, on Monday, the 14th of May, 1866, at eight o'clock p.m. Dr. J. A. Spencer read a paper "On the Mode of Action of Strychnia," and thereafter Dr. Strehli Wright exhibited an interesting series of the diffusion figures of liquids by means of the oxy-hydrogen microscope.

RUPTURE OF UTERUS; GASTROTOMY SUCCESSFULLY PERFORMED.

DR. E. MILES WILLETT relates a case of rupture of the uterus for which gastrotomy was successfully performed. The patient after having previously given birth to two still-born children, was seized with her third labour, March 20, 1865. It showed nothing remarkable in its progress until twelve hours after its commencement, when Dr. Frayser, the attending physician, called in Dr. Willett to assist him. They then found the patient somewhat restless and disturbed in mind. She had vomited freely, and was throwing up bile when we entered the room, but had not had a labour pain for half an hour. The blood in the vagina, the recession of the head, the absence of labour pains, and the irregular surface of the abdomen, through the walls of which could be distinctly felt an elbow, made the diagnosis of rupture of the uterus absolutely certain, although the attendants did not think that she had suffered much, and could not remember any particular agonizing pain. After consultation, the performance of gastrotomy was decided on, but the operation could not be commenced, owing to a difficulty in obtaining the consent of the friends of the patient, until two hours and a half after the rupture occurred. Assisted by Drs. Frayser and Grant, he made an incision in the median line, through the skin and cellular tissue, from below the umbilicus to within an inch of the pubes; but as this would not give sufficient room, it was extended upwards and to the left of the umbilicus. The peritoneum was then opened, and with a probe-pointed bistoury, guided by the finger as a director, the incision was completed. It was found that the child and placenta had been expelled by the uterus into the cavity of the abdomen, the child's head rested on the brim of the pelvis, and the uterus had contracted sufficiently to prevent exhausting hæmorrhage. After removing them, the blood and amniotic fluid was sponged out as well as could be done, the edges of the wound were drawn together with interrupted sutures and adhesive plaster, the body-bandage adjusted, and cold applications ordered. During all this time the patient was fully under the influence of chloroform. The pulse was 96, and sufficiently full before the operation; one hour afterwards it increased to 110. During the night she took six drachms of elixir of opium. No untoward symptoms retarded the recovery.—*Memphis Medical and Surgical Journal.*

ICE IN CHOLERA.

A CORRESPONDENT of the (Calcutta) *Englishman* gives an account of the successful treatment of a case of cholera, apparently in an advanced stage, by the application of ice to the spine, as recommended by Dr. Chapman. The writer says:—"On Sunday, the 25th Feb., about 10-30 a.m., my servants requested me to go and see a man who, they said, was dying of cholera, and to give him some medicine. I proceeded to the place, where I found a man lying on the ground in the greatest agony, with the usual symptoms of cholera—vomiting, &c. He was much emaciated, and to me appeared rapidly sinking. I had no medicine in the house. I ordered one of my servants to go round among the neighbours and try to get some medicine, but in this I was unsuccessful. I recollected, however, having read in the *Times* an article bearing the signature of John Chapman, M.D., 25, Somerset-street, Portman-square (of which I had taken a note), in which the writer advocated the use of a bag of ice down the spine. Feeling that if I did no good, I could, under the circumstances of the case, do no harm, I made up my mind to try whether ice would do any good. I now proceed to give you an account of what I did, and as to what the results were. 10-30 a.m.: The man, a Mussulman, a hackery-wallah, arrived with his own and other hackeries from Calcutta. He had been for two or more hours purging and vomiting violently; voice scarcely audible; pulse imperceptible; hands, arms, legs, and feet quite cold. He was throwing his legs about and twisting

his body in great agony; he complained much of thirst. I gave him water with a little carbonate of soda in it. He appeared to be sinking fast. 11:0: I procured some ice from a neighbour. Having no gutta-percha bag, I took the leg of a pair of flannel trousers and made a long bag to reach from between the shoulder-blade to the bottom of the spine, of a width of three inches; into this I put broken ice, and applied it to the spine. After I had applied the ice the purging and vomiting ceased, and by 11:20 the spasms were much diminished. 11:30: The patient was much easier. On questioning him he said in a very low voice that he felt easier. A little before twelve I found that his pulse was perceptibly stronger, and that his arms and legs, which were previously as cold as stones, began to be slightly warm. The flannel in which the ice was put was now saturated with water, and as Dr. Chapman said the cold was to be a dry not a wet cold, one of my natives suggested the use of a bottle, on which I got a preserved-fruit bottle into which I put the ice, and had the bottle held against the spine. 12:30 p.m.: No more vomiting, &c., the arms and legs getting warmer; no pain, very great thirst; I let the man drink as much as he liked. From this time till 1:30 I kept the bottle of ice on his back, when, finding that his hands, arms, legs, and body were becoming hot as if he had fever, I removed the bottle of ice, and as I was about to leave my house for tiffin with a neighbour I told my khansamah if fever came on to put in the place of the ice-bottle a bottle of hot water. 4:30: I returned to the man. He was fast asleep, and a more deadly object I never saw. At 5:30 he awoke and asked for food. I gave him some thick conjee with sugar and brandy. 7:30 a.m., Monday, 26th: The man is sitting up; convalescent, but weak. He wants to take his bullocks and hackery away. The above are the facts of the case."—*Medical Times and Gazette*, April 28, 1866, quoted from the *Homeward Mail*.

THE USE AND ABUSE OF POULTICES.

IN his lectures recently delivered at the College of Physicians, Dr. Richardson made the following remarks on the subject of poultices:—

The application of moist heat in the form of poultice to suppurating parts requires, I think, remodeling, in order that it may be placed on a true scientific basis. I am afraid that the common recommendation, "You must put on a poultice," is too often among us all an easy way of doing something about which we are not quite sure, and concerning which it were too much trouble to think long. From what I have recently observed, I fear that mischief is often done by a poultice, which might well be avoided. The people have always a view, that a poultice is applied to "draw," as they say—a term in truth which, though very unsophisticated, is in a sense a good term, for it means what it says. The question for us is, whether it be sound practice to carry out as a general rule the "drawing" process, either by fomentation or by poultice.

When a part is disposed to suppurate, the first step in the series of changes is an increased flow of blood through the capillary surface, followed by obstruction, and thereupon by an excess of sensible heat derived from the friction that is set up. Then follows transudation of liquor sanguinis into the connective tissue, and its transformation, under the influence of heat, into what is called purulent fluid. When to the part in this state we apply moist heat we quicken suppuration, mainly by upholding the temperature: at the same time we secure the transference of water from the moist surface into the fluids of the inflamed part, by which tension of tissues is produced, and in the end yielding of tissue at the weakest point.

When the suppurating surface is circumscribed, the rapid induction of the process may be attended with little injury; but when the surface is large and when the exuded fluid is thrown into loose structures where it can burrow readily, the practice, I think, can-

not be good to extend the mischief. Hence, in the treatment of carbuncle and phlegmonous erysipelas it cannot, I opine, be sound practice in the early stage to apply moist heat. Experience also, not less than principle, warrants this conclusion. In cases of carbuncle especially, I have of late altogether avoided the application of moist heat in the early stages; and I feel assured, with good results.

But when, in the course of local disease, suppuration is actively established, and is naturally circumscribed; when the increased temperature of the part has fallen to or below the natural temperature, then the value of moist heat comes on with full force; then the tension which is exerted determines the escape of fluid at the weakest point of the surrounding tissue, and when the fluid escapes or is liberated by the knife, the escape for a long period is aided by the application of moist heat.

The continued application of moist heat for a long time after the escape of purulent fluid is again, I conceive, indifferent practice. It sustains discharge; it sets up unhealthy decomposition of fluids; it produces a thickened soddened condition of skin, most favourable to the production of sinus; and it retards recovery. When a surface is freely open, and suppurating, dry and not moist heat is the remedy. We are in want in these cases of a simple invention; we require something which we can apply as readily as a poultice, which shall keep up the temperature of the part, and at the same time take up moisture, and gently desiccate, without injuring the tissues.

ARSENIC IN HÆMORRHOIDS.

LAST summer a friend suffering with "hay-asthma," called upon me for a prescription. He likewise was a martyr to hæmorrhoids, and had been for years; in vain he had submitted to the ligature, to nitric acid, to incision and to excision—each of these relieved for a time, and then the trouble returned. Fowler's solution was prescribed for him, with reference solely to the asthma. At the expiration of a week, there was no improvement in the difficulty for which the arsenic was administered, but there was a remarkable change for the better in the hæmorrhoids, and a further continuance of the remedy relieved him entirely. Since that time occasional relapses have occurred, but they yielded quite well in a few days to eight drops of Fowler's solution three times a day. It is now upwards of thirty years since Sir Charles Locock pointed out the value of arsenic in the treatment of *atonic menorrhagia*; and quite recently Dr. Handfield Jones ("Functional Nervous Disorders") explains the results by the influence arsenic exerts in producing contraction of the bloodvessels. Doubtless this is the way too in which it acts upon the enlarged hæmorrhoidal vessels, although its application in the treatment of such diseased state is to me entirely novel, and the discovery purely accidental. That it does good I do not doubt for a moment; but that it should be resorted to neglecting the condition of the intestinal canal with reference to proper secretion and evacuation, would only tend to discredit by failure what I believe will be proved to be a valuable application of an important remedy.—*Dr. T. Parvin, Cincinnati Journal of Medicine*.

THE Medical Congress of France for 1866 meets at Strasbourg, It opens August 27th, and will last six days. Foreign medical men will be admitted members (without subscription) on application to the Secretary, Dr. Hecht, 42, Rue des Grandes-Arcades, Strasbourg. The following is the programme of subjects for discussion decided on by the Committee:—1. The Mode of Propagation of Cholera; 2. The Treatment of Constitutional Syphilis; 3. Ovariectomy and the Extirpation of Fibrous Tumours of the Womb; 4. Histology in its relation to Pathology and Clinical Medicine; 5. Anæsthesia in Surgery. Whoever desires, by writing or verbally, to take part in the discussion of these special subjects, must give notice to the Secretary eight days at least before the opening of the Congress.

Reviews.

ON THE USE OF THE SPHYGMOGRAPH IN THE INVESTIGATION OF DISEASE. By BALTHAZAR W. FOSTER, M.D., Professor of Clinical Medicine in the Queen's College, Birmingham.

DR. FOSTER, in this *brochure*, read, in the first instance, as a communication to the Midland Medical Society, records an interesting and very valuable series of experiments on the characteristics of the pulse in various diseases, and has illustrated very forcibly the changes in amplitude, tension, and rapidity of the pulse observed by him under more reliable conditions than usually exist. We have been accustomed

to depend altogether on the *tactus eruditus* for our diagnosis from the pulse, and to content ourselves with the observation of the two or three most manifest changes in the circulation; but Dr. Foster's observations show that there are many other elements in the pulse which are never noticed by the finger, and yet can be clearly shown by the sphygmograph. The instrument is not new to our readers, who may have seen an illustration and description of it in our columns some months ago, and who have had Dr. Anstie's essay on the subject before them; but it has been in some respect modified by Dr. Foster, and we, therefore, append his illustrations and his description of the instrument as employed by him:—

"The accompanying woodcut (Fig. 1), copied from Marey,

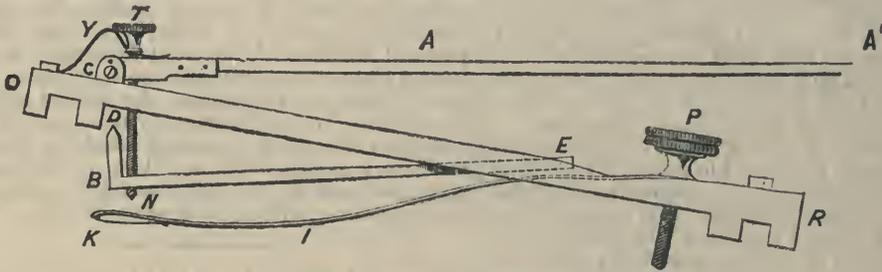

Fig. 1.—Marey's Sphygmograph.

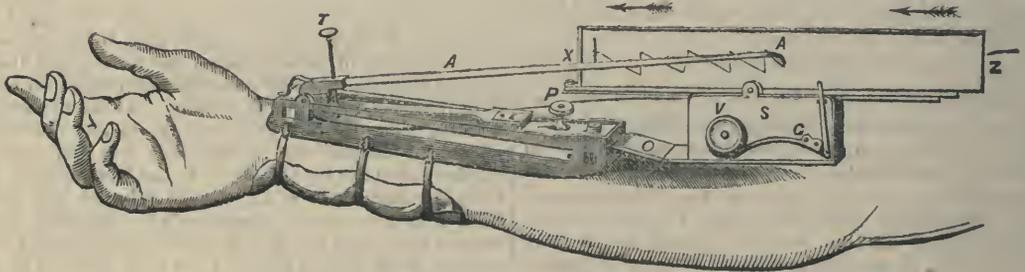

Fig. 2.—Sphygmograph applied to the Arm.

shows us in the interior of the frame (q n) the essential part of the instrument, which consists of a flexible steel spring (I), covered on its under surface at its free extremity with a convex plate of ivory (κ). This ivory plate rests upon the artery to be examined, and, by virtue of the elasticity of the spring (I), exerts a certain pressure upon it. Each pulsation of the vessel raises the spring slightly at κ, and the multiplication of this movement is obtained by means of a very light lever (A), which moves upon a pivot (c). The elevation of the spring is transmitted to the lever, very near to its centre of movement, by means of a bar of metal (B E), which moves round the point (E); this bar terminates in a vertical plate (n d), and is pierced by a screw (T). When the screw acts upon the spring, the connexion is established between the spring and the bar, and the movements of the spring are transmitted to the bar, and through its vertical plate to the lever. In order to insure the transmission of the movement, the plate (B N) must be in contact with the under surface of the lever; by means of the screw (T) we can arrange this, and regulate the interval between the point of the plate (B D) and the under surface of the lever. In order that the lever should not be projected too much upwards by sudden movement, and also that it should overcome any slight friction experienced in the paper at its terminal point (A), a small spring (v) rests upon its fixed extremity, and presides over its descent. The screw (P) enables us to regulate the amount of pressure exercised upon the artery by the spring (I). The woodcut (Fig. 2), modified from Marey, shows the instrument placed upon the arm

over the radial artery in the position for use. The lever (A) is here seen to carry at its free extremity a little pen, which, filled with ink, registers its movements upon the paper which covers the plate (x z); this plate is moved at a uniform rate in the direction indicated by the arrows, by means of watchwork placed beneath in the case (s). Ten seconds are occupied by the passage of the plate. The button (v) enables us to wind up the watchwork; and the small regulator (g) starts the plate, or stops its motion, as desired. The application of the instrument I have found much facilitated by the use of elastic bands, instead of a silk lace, as recommended by Marey. These bands embrace the arm, and are hooked on to the small projecting points on the metal framework, as seen in the diagram. The addition of a pad* to the under surface of the arm renders the instrument more easy to the patient, and prevents any pressure from the bands."

Dr. Foster illustrates, firstly, the natural pulse movement; then the changes from loss of arterial elasticity in old age; and, lastly, the effect of increased or diminished force and frequency in various diseases. In Dr. Foster's hands the instrument seems to have registered with uniform accuracy, and we believe it will be found a valuable aid to the careful observer, who cannot have a more useful introduction to its use than Dr. Foster's *brochure*.

* I am indebted to my clinical clerk, Mr. Waters, for the suggestion of the pad.

THE ALKALINE PERMANGANATES AND THEIR MEDICINAL USES. By JOHN MUTER, late Assistant Demonstrator in Chemistry, Andersonian University Glasgow. London: John Churchill. Pp. 48.

THIS pamphlet is devoted to an exposition of the advantages claimed for the liq. permanganates potassæ, better known as Condy's fluid. It is hardly necessary to remind our readers that this solution owes its especial virtues as a disinfectant and as an internal medicine to the very remarkable instability of its combination with oxygen, which it evolves in the nascent state with the greatest readiness, and therefore effects every object which oxygen itself can serve. The value of its functions as a disinfectant is well known, and they are largely utilised in surgery for the neutralisation of effluvia and the correction of offensive breath. The permanganate of potash has been admitted into the British Pharmacopœia as an internal medicine with the following claims to general use:—

"1. They can be taken in doses of from half a grain to two grains (equal to from one to two drachms of the officinal liq. potass. permangan.), often repeated, and continued during a lengthened period, without inconvenience.

"2. They diminish the frequency of the pulse, and to that extent aid the function of respiration. This effect is apparently owing to their supplying the system with oxygen, of which they contain so large a proportion.

"3. Acting chemically, they perform the part of purifiers of the blood, consuming morbid matters generated in the system itself or communicated from without, and thus second the renovating action of respiration. They likewise cleanse, by oxidation, the *primæ viæ* and the *ingesta*, and act as antidotes to morbid and putrescent excrementitious matters.

"4. By reason of the facility with which they are decomposed and their base set free, the alkaline and earthy permanganates operate as antacids and alkalizers of the fluids of the body.

"5. As compounds of manganese, they produce the ordinary constitutional effects of this substance, which have conferred on it considerable reputation in the treatment of jaundice, hypochondriasis, torpid liver, and certain forms of dyspepsia.

"6. To whatever cause assignable, the alkaline permanganates must be admitted to possess the property of mitigating in a remarkable manner the thirst which is so severely felt in diabetes and most febrile diseases."

The qualities which are so much to be desired in the permanganates as oxidising agents make them incompatible with many forms of prescription, and Mr. Muter advises their exhibition as follows:—

"Few compounds are so susceptible of decomposition by organic and certain other substances as the salts of permanganic acid. On this account it is necessary to be very guarded in prescribing them in combination. The following are the principal substances used in medicine with which the permanganates are incompatible:—

"All organic bodies, tinctures, extracts, decoctions, infusions, medicated waters, syrups, confections, wines, unmedicated as well as medicated, hydrochloric acid, tartaric, citric, benzoic, gallic, and other organic acids (acetic excepted) and their salts, glycerine, the alkaloids and their combinations, iodine and iodides, arsenites and all metallic salts whose bases are capable of being converted into peroxides. The compatible substances are these:—Mineral acids (hydrochloric excepted), acetic acid, alkalies (including ammonia), clean alcohol, alkaline earths and their carbonates, almost all alkaline salts (borates and phosphates included), except tartrates and citrates, purified charcoal, and all metallic salts whose bases are not susceptible of peroxidation, such as nitrate of silver, sulphate of zinc, &c. In every instance in which the permanganates are prescribed in combination, it is important that the administration of the medicine should take place with as little delay as possible, since many substances which are compatible with them for prescription will, after a certain lapse of time, effect their decomposition. In this category stand alcohol, ammonia, acetate of ammonia," &c.

The author's statement, though of course *ex parte*, is supported from beginning to end by such reliable authorities as Bence Jones, Ozanan, Hillier, Basham, and others, whose recommendation is a guarantee of the truth of his statements, and will secure attention from the profession for the statements which the pamphlet embodies.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 30, 1866.

THE MEDICAL COUNCIL AND THE AMENDED MEDICAL BILL.

WE last week presented to our readers the Draft Amended Medical Bill as it was received by the General Medical Council from the hands of the Home Secretary, Sir GEORGE GREY. As it came into our possession only as we were going to press, we had no opportunity of offering any observations as to its provisions, and we contented ourselves with merely recommending it to the support of the Profession. Since that time it has been submitted to a Special Committee of the Medical Council, and has been discussed by the Medical Council itself, the result being that some alterations have been suggested for adoption by that body, and it is hoped that they will be acquiesced in by the Government.

It may be observed generally that the Bill of the Government agrees in nearly all respects with that recommended last year by the Medical Council, and its contents are therefore satisfactory, but there are one or two points which have excited very lively discussion in the Council, and on which there will probably be some difference of opinion between the Council and the Government. The love of quackery and the inherent desire on the part of our Legislators for its protection would appear to crop out here and there in any and every measure designed for the regulation of the Medical Profession, and the Council has done well to scan the Amended Bill with the closest scrutiny lest, perchance, the new measure should merely perpetuate the defects and shortcomings of the former one.

It will readily be understood that the great struggle to be made by the Council and by the Profession is for the alteration of the notorious fortieth clause, which, as it stands in the existing Act, has afforded no protection whatever to the legitimate practitioner against the ignorant and unprincipled pretender. Now the Government proposes to substitute for this clause the following, which, for the sake of its thorough comprehension, we again print:—

"If any person practising medicine or surgery, or engaged in the cure or treatment of diseases or injuries, not being registered under the Medical Acts, takes or uses any of the designations enumerated in Schedule (A) to the 'Medical Act, 1858,' as amended by Schedule (B) to this Act, or by any other of the Medical Acts, or the designation of physician, surgeon, doctor of medicine, or apothecary, or any other designation used by or used to dis-

tinguish duly qualified practitioners of medicine or surgery, or any class thereof, or the designation of professor of medicine or of professor of surgery, he shall for every such offence be liable on summary conviction to a penalty not exceeding *twenty pounds*."

This is a great improvement on the former clause, which prohibited only the assumption of certain medical titles, but the new clause prohibits the assumption of medical titles *by persons practising medicine*, and not registered under the Medical Act. But still it will be seen that persons are only prohibited, under the penalty, from assuming certain titles, including *Doctor of Medicine*, but they are not prohibited from using the title of Doctor, and the Council, in its Report on the Bill, very properly objects that the substitution of the words Doctor of Medicine for Doctor (as proposed in the amended Bill of the Council), will very materially weaken the clause; because if this substitution be retained, many unqualified persons will continue to practise medicine as they do at present, calling themselves "Doctors," but not "Doctors of Medicine," and thus evading the penalties. The rejoinder to this objection that a person calling himself Doctor might assert that he was a Doctor of Divinity, or Philosophy, or Law, and ought not therefore to be liable to punishment, is readily met by the argument that only those will be liable to be fined, who, in the language of the Bill, are "practising medicine under the title of Doctor," and the Council is therefore advised to represent this matter very specially to the Home Office.

There is another point in the Government Bill which is calculated to excite some misgiving—namely, that there appears to be an unnecessary anxiety to open the Register to foreign degrees and diplomas. Now there can be no doubt that many foreign degrees are very creditable to their possessors, and ought to be registered, but on the other hand, there are many which are quite worthless, and it is a very difficult matter to decide upon their relative value. Again, it is possible, that if undue facilities for registration were offered in the British Register, many persons who had been compelled to quit their own land in consequence of their misconduct, would take refuge here in large numbers and thus bring discredit on the Medical Profession in this country.

BLACK DEATH—CHOLERA—CEREBRO-SPINAL ARACHNITIS.

If we depart from our ordinary practice, and specially call the attention of our readers to our Hospital Reports as we now beg to do, it is because of their unusual and pressing importance.

In a recent report the experience and views of Dr. LYONS were laid before the profession, with regard to what was termed "black death," and it is because extracts or professed quotations from that report were introduced into some of the daily papers, that we think attention should be directed to the subject afresh.

There is no occasion for any popular panic in this matter; and our professional readers should, wherever

necessary, use their influence with the public to dissipate any such idea. The facts, as they have come under the observation of Dr. LYONS and others, were of course sufficiently startling to cause a minute and immediate inquiry into them; but when the pathological researches of that gentleman and others (which we hope shortly to lay before the profession) are read as they should be, it will be seen that there is no ground whatever for expecting the whole community to turn black in the face and die almost suddenly; and our younger brethren should not be in any hurry to give a bad name to some of our common acute diseases which may, in some respects, present to them an aspect differing from the orthodox and wordy descriptions of book-makers.

So much for a panic on one question, yet another remains.

One of the most extraordinary cases on record occurred within the last few days under the care of Professor BANKS, in Sir Patrick Dun's Hospital. The particulars will be found in this day's Hospital Reports, and we shall not here refer to them further than to draw the moral. An inexperienced physician might have mistaken this case for cholera, which, in some respects, it resembled; might have hastily expressed such opinion to others, and so set all the newspapers frightening the entire community. It fortunately happened, however, that the patient fell into the hands of a physician of experience who remembered the epidemic of cerebro-spinal arachnitis which visited Ireland in 1846; and who also remembered the epidemic cholera which more than once in the present generation visited this country. Nothing more strongly tends to show the value of educated experience than all this, applied as we see it in the case to which we refer; and when we add that the post-mortem examination was conducted by Dr. BENNETT, an anatomist of high repute, and that his report confirmed the necessity of prudence and caution in pronouncing hastily on cases of the kind, we need no further argument to prove, that where a startling and fatal case of a very rare kind occurs, it is most desirable that direct pathological proof of an opinion which may carry with it grave public results should be given to the profession.

Notes on Current Topics.

SCOTTISH UNIVERSITY REPRESENTATION.

FROM a notice in another part of our columns it will be seen that the Royal College of Surgeons of Edinburgh have resolved to petition Parliament in favour of the allocation of two members, instead of one, to the Scottish Universities. This is but a reasonable request, whether we consider the numerical importance of the constituency to be represented (considerably above 4000, and exceeding in numbers the combined constituency of the University of London and the Queen's University in Ireland, each of which are to have one representative), or the national character of the Universities to be represented. It is enough

to raise the ghost of the late Lord Eglinton, and make the Scottish Lion even more rampant than usual, to have all the Universities of Scotland shoved off with only one member, while the national Universities of England, Oxford, and Cambridge, and that of Ireland, the Dublin University, have each two. We understand that the Royal College of Physicians of Edinburgh are also to petition in this matter, and we hope that this good example shall be followed, and that speedily, by every body of learned men throughout the kingdom.

THE EDINBURGH VETERINARY SCHOOL.

THE late Professor Dick, whose lamented decease we so recently chronicled, has evinced the great and abiding interest he took in that school which he founded, and of which he was for long the sole teacher, and always the principal ornament, by leaving in trust to the magistrates of the city of Edinburgh the buildings erected by himself to be employed in all time coming as a School of Veterinary Science. For this purpose he has also bequeathed to the same parties the valuable museum of Veterinary Pathology accumulated in the course of more than half a century of an active professional life, and he has left the bulk of an ample fortune to endow this school, and thus secure its permanency for the instruction and benefit of future generations. By his own unaided energy, his indomitable perseverance, and his force of character, Professor Dick founded and made this School what it now is, one of the most famous seminaries of the Veterinary art in the world, whose pupils are scattered over the habitable globe, and who are everywhere received with that respect which is due to those who skilfully practise an honourable profession. We in our day can scarcely form an estimate of the enormous influence for good which Professor Dick has exercised upon the education and the status of the Veterinary profession, and those of us who, of late years, have perhaps been a little inclined to regard him as somewhat behind the age in scientific acquirements, might well hesitate to express that opinion when we thought of the vast change produced by the untiring energy of one man in the course of fifty years. Rome transformed from brick to marble at the bidding of an emperor, is nothing to the spectacle of an educated profession reared from the mire of quackish ignorance by the exertions of one humble unit of the people. It is true that the Highland and Agricultural Society of Scotland, foreseeing the great benefit to be derived by the agricultural profession from a well-educated veterinary profession, at a very early period resolved to grant diplomas of ability to practise the Veterinary art to those of Professor Dick's pupils who were found qualified to possess them after an examination made by the most distinguished practitioners of the Veterinary art, aided in regard to the scientific departments by some of the ablest members of the Edinburgh Medical School; but had it not been for Professor Dick there would have been no pupils to examine, and it is perhaps not too much to say that we would possibly even yet be dependent on foreign sources for our supply of veterinary skill. How great the loss that would have thus accrued to Scotland may in some measure be guessed, when we see the advanced position she has taken in regard to the treatment of the cattle plague, and reflect on what that position would have been had Professor Dick and his school never existed. As yet we do not know, and can hardly estimate how much we

owe to that one man; and yet, in the face of all this, in the face of the fact that the diploma of the Highland and Agricultural Society has been accepted as a legal qualification both by Government and by all other bodies requiring such a diploma, and in the face of the fact that the possessors of this diploma have never been found wanting when called upon, there is now before Parliament a Bill to restrict the legal title of Veterinary Surgeon to the possessors of the diploma of a London College. Why should we not also have a Bill to restrict the legal title of Surgeon or Physician to the possessors of a London diploma? But that will come by and by, and if we do not resist this commencement of centralization, we shall presently have one central college, with peripatetic deputations to examine our medical as well as our veterinary students. It is specially necessary, forsooth, "that an improved *status* be given to Veterinary Surgeons" at this present time. So it may be in England, when the fearful mortality from rinderpest betrays anything but exceptional scientific knowledge or skill; but in Forfar and Kincardine, in Aberdeen and Ayr, the pupils of Professor Dick have shown by their skill in the treatment and their success in the stamping out of rinderpest, that no London diploma is needed to increase their skill, nor could its possession improve their *status*.

We understand that the Royal Colleges of Physicians and Surgeons of Edinburgh, and the Highland and Agricultural Society of Scotland, propose to take conjoint action, not to oppose this Bill, to which there is no objection, so far as England is concerned, but to secure that similar privileges be granted to diplomas issued by a Scottish College of Veterinary Surgeons yet to be constituted, whose diplomas shall take the place of those hitherto issued by the Highland and Agricultural Society. This is certainly a step in the right direction, and had our Medical Council evinced any capability of regulating the affairs of our own profession, we should have proposed that they should have also had the regulation of the curriculum of study, and of the examinations for the diploma of this subordinate but hardly less important branch of it. As it is William Dick has not lived in vain. His life was spent in founding a School of Veterinary Surgery, and his grave is but the trench in which to lay the first stone of that building destined to raise that School to a College.

THE VISITATION OF EXAMINATIONS.

It is already known that the Medical Council, in accordance with powers vested in it by the Medical Act, has commenced a system of visitation of the examinations conducted by the qualifying bodies in medicine and surgery, and some of the results are now printed. The machinery by which this object has been carried out is at present very imperfect; but still the reports furnished by the visitors are very interesting, and we shall publish them as soon as our space will permit. Those who are acquainted with the *personnel* of the members of the Medical Council will perhaps in some instances be inclined to ask themselves why certain persons have been appointed to supervise certain examinations, and what their peculiar capacities were for the performance of such a duty; but on the whole we believe that the selection has been judicious, and certainly has always been fair. It has been very broadly hinted by a contemporary that some of the reports in reference to certain of the examining bodies in London contained such severe strictures on the proceedings that

the documents would be withheld; but such is undoubtedly not the case, for the reports are all printed and apparently in full, and they speak generally in favour of the mode in which the examinations are conducted. In some cases, however, some very judicious suggestions are offered, in which we entirely coincide, and to which we shall direct attention at a very early period.

GREEK AS A NECESSARY ELEMENT IN MEDICAL EDUCATION.

WE rejoice to announce that, after very considerable opposition, it has been determined in the Medical Council that the Greek language shall form one of the compulsory subjects in the preliminary examination in Arts of all medical students after the year 1869. The resolution embodying this important change was vehemently opposed by most of the representatives in the Council of the Scotch Universities and Colleges, in which institutions, as is well known, not only has the Greek language never been compulsory in the case of medical students, but preliminary education has been enforced only in very late years, and since the passing of the Medical Act. If the introduction of the Greek language as a branch of preliminary education for medical students had been a mere modern innovation there might have been some reason for the opposition manifested, but in fact many of the medical examining bodies have long required it of medical candidates, and a few who have lately made it optional instead of compulsory have done so only in consequence of the laxity of the Medical Council. It was very truly observed that a youth who is unable, between this time and 1869, to master the elements of the Greek language, is unfit to enter the medical profession; and if this resolution on the part of the Council should have the effect of making the profession more select, the result will be a matter of congratulation rather than of regret.

THE length to which our special report of the proceedings of the General Medical Council extends, and its vast importance to the profession, must excuse us for the postponement of many important communications which stand ready for publication. For the same reason we are obliged to postpone a part of our own comments on the proceedings, and on other important questions, which, we trust, will not be of less interest as a supplement to the reports.

Correspondence.

WE are not to be assumed to agree with the views of our Correspondents whose communications we insert for the purpose of affording opportunity for the enunciation of all shades of opinion in things medical. Our revision of letters is, therefore, confined to the removal of statements or expressions which we consider unsuitable or irrelevant to the subject in hand.

QUACKERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is not astonishing that medical practitioners are complaining on account of the very extended and shameful quackery which has invaded the greater towns of the united kingdom. The principal cause of such a state of things is, that the legislation of therapeutical and pharmaceutical science has not yet reached the same point of severe control which exists on the Continent. It is disgusting and disgrace-

ful for any person, more especially for scientific medical men, to read the odious advertisements, scandalous pamphlets and bills, which are placarded and distributed on the streets.

In conversing with a medical man I was told that this was a free country, and nothing could be done for the present to eradicate such an abuse. As a foreigner, I know perfectly well how to appreciate the blessings of the liberty of this country; but it is my conviction that in every thing which concerns the health of the public there ought to be a most strict control upon quacks and cheese-chemists, who, for the sake of money, sell poison.

When Jacob Bell instituted the Pharmaceutical Society in England, he says, in one of his Repertories: "We have many chemists, but too many cheese-chemists."

These kind of shops, and the shops of quacks all filled with coloured water bottles, are called by the ignorant people "Doctors' Shops;" they are the destruction of many a young man when he has fallen into their snare; money and health are gone for ever. If the law of the country is not able to root up such an abuse, the pen will be able at least to initiate those that are ignorant that they may understand what quackery signifies; every person will abhor reading the malicious expressions of pamphlets and bills on the streets.

There is one who, in a greater style takes up in his advertisements the name of an eminent medical man in Paris with whom I have been acquainted for more than twenty-years, a scientific and skillful man, who never would have written such mean expressions which that high-styled quack has the boldness to make use of in all the papers of this town.

Considering their previous qualities, the reader will comprehend the boldness which these men profess in undertaking to cure people of all dangerous diseases, or rather to rob them of money and health.

Quacks are, in general, without any education; one has been a servant in a disorderly house; one a traveller for selling needles; another a chevalier d'industrie; and another a pupil of a quack with an anatomical museum, and many other ruffians who are clever enough to make dupes and victims.

Some of the quacks have a diploma as M.D. from an University in the United States, which they obtain without having been there from an American agent, who charges them for such a document from £4 to £6, and such an M.D. can scarcely write his name.

To clear the philosophical medical science from these scandalous subjects, and to save the innocent and ignorant from the snare of quacks, we will in a short time lay before the public a pamphlet which will contain all details concerning quackery, for the purpose of entirely eradicating their odious machination.—Yours truly, H. KOLZENSKY.

Late Governmental Physician in Russia.

POOR-LAW MEDICAL REFORM AND VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your giving insertion to the annexed letter, addressed to the Poor-law Board, but to which I have not as yet received a reply. I have been in correspondence with members of the Select Committee on Vaccination, and have forwarded my opinion on the Government Bill to the Committee. Mr. Bruce, the Chairman, has written to a Member of Parliament as follows:—"Should the Committee on the Vaccination Bill decide upon taking evidence, I will not fail to bear in mind your desire that Mr. Griffin should be examined."

Since the last list of subscriptions was published I have

received the following:—Eaton, F., Grantham, 10s.; Hulme, J. D., Blaby, 5s.; Garlick, F. S., Halifax, £1; Crowther, T., Halifax, 10s.; Nowell, W., Halifax, 10s.; Mackinder, D., Gainsborough, 5s.—I am, &c.,

RICHARD GRIFFIN.

12, Royal terrace, Weymouth, 21st May, 1866.

12, Royal-terrace, Weymouth, 17th May, 1866.

MY LORDS AND GENTLEMEN.—On the 3rd February last I forwarded to your honourable Board the draft of a proposed Bill "for the better Regulation of Medical Relief to the Poorer Classes in England and Wales," which was acknowledged in these words—"I am to inform you that the provisions contained in the Bill shall receive the consideration of this Board." My object in now writing is to ask you to do the Poor-law Medical Officers the favour to receive a deputation from them, in order that they may urge upon your honourable Board the desirableness of sanctioning some, at least, of the propositions named by them in their proposed Bill, and that you will recommend them to Parliament for adoption, either as a distinct Bill, or as part of the intended Poor-law Continuance Bill. Any day after next Saturday week that the Board may fix to receive a deputation will give time for me to communicate the fact to the Poor-law Medical Officers through the medium of the medical journals, provided the reply be received on or before next Tuesday, otherwise I must ask for the postponement of the deputation until the following week.—I have the honour to be, my Lords and Gentlemen, your obedient servant,

RICHARD GRIFFIN, Chairman,
Poor-law Medical Reform Association.

The Poor-law Board.

UNDERCHARGING FOR MEDICAL SERVICES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—Some time ago we had occasion to address you in reference to the grievance of "Undercharging" for medical services, which prevailed largely in this district. You will remember we stated that some of our members stooped so low as to charge sixpence for a visit or advice, or drive eight miles to do the duties of an accoucheur for three or at most four half-crowns.

We assure you, Sir, we would have felt gratified had it been in our power to say that our letter and your able comments had borne good fruits, but we have every reason for believing that sixpenny fees are as rampant as ever with the parties for whose special benefit our letter was written. Since the date of our last communication we have learned a good many facts, all tending to prove that in social position our profession in this district cannot get much lower. The following significant fact may astonish some of your London readers:—In our town we have five practitioners, and not one is assessed an income; in other words, the largest sum derived from actual practice by any surgeon is something less than £100 per annum. We have at present in our midst a surgeon whose practice includes a radius of at least fifteen miles—a man who is scarcely ever off the road, and yet we find him in the Appeal Court, claiming and obtaining exemption from taxation; satisfactorily proving, as he did, that for his never-ending duties his remuneration was something like £80 per annum. We think we hear you conclude that such a deplorable state of affairs is attributable, not to the community, but to the practitioner. In this we entirely concur, and such is the conclusion of the majority of the very classes he flatters himself he is favouring. It is, in fact, the result of the abominable sixpenny rate of charging. We have no reason for supposing that our community is below average as regards worldly substance, and we feel certain that in that respect they are at least equal to the districts on either side, where the medical men hold positions and appearances in every way compatible with the honour of our profession. We can say, for our own part, that it is very rare for a patient to grudge our charges, and we ask either a fair thing, or if a case of true charity nothing. We consider a medical man would be cruel indeed who would refuse his

assistance in a really charitable case, even though he entertained no prospect of ever receiving any remuneration; at the same time we do not admit this an excuse for a man to perform medical duties to all classes of society for a fee that at the least would be paid to a hired labourer. Such a style of carrying out practice, we believe, tends as powerfully to lower the profession as the vilest form of quackery. We assure you, Sir, it is not our nature to be always making grievances, but the above is such a preposterous evil, and the results are so disastrous to our profession, that we would consider we had fallen short of our duty did we stop railing against it until matters are put on a proper footing. We know we have the profession on our side, and, as far as we can judge, a large share of the community, who can feel the force of the proverb, "A man should be just before he be generous." We only ask a fair remuneration for our trouble, so that we may be able to maintain a position becoming the profession of medicine, and feel no dread of the Bankruptcy Court.—We are, Sir, yours truly,

MEDICUS ET CHIRURGUS.

THE EXAMINATION FOR MEMBERSHIP OF THE ROYAL COLLEGE OF SURGEONS, IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—There has been a little sense and a great deal of nonsense written lately about the examination for membership of the Royal College of Surgeons, Dublin; but there seems to me to be one subject connected with it which is very little noticed—i.e., the conduct of the students. I believe that the students pass far too much of their time in what Sir D. Corrigan, in his admirable introductory the other day, calls "sight-seeing." They hear of some grand surgical operation which is to take place at one of the hospitals—there they flock, and count the number of minutes that the operation lasts; but when the "show business," as Mr. Artemus Ward says, is over, how many wait to see the wound dressed, or how few return to see how the patient is going on? Yet this, as they will afterwards find, is a most important part of the case. Perhaps they hear of some interesting medical case; they go and take a look at it—but do they examine the patient for themselves, or read it up so as to know it again? The same way in midwifery; they run to see the forceps applied, or the craniotomy forceps used. Could they make a decent attempt to do either for themselves—aye, even third year's men—if you place them in a country cabin, without any assistant but some old hag, who threatens to "swear agin you?" No. They stroll into the dissecting-room, pity some poor "muff" who is dirtying his hands to pick information out of his subject, make noises suitable for the top gallery of the Queen's during lecture hours, talk of the "Head Centre," go to grind without any preparation, spend the evening in amusement, and fancy that they have done a hard day's work, when in reality they have learned nothing of the slightest practical use to them. It's all humbug for these men to say that the examination consists only of cruxes which they can learn no place but at grind, whereas they never attempted to learn anywhere else; and if they do manage to struggle through, they come out swearing that there is nothing like leather, especially if they have been "nibbled" into taking a private hour. Grinding is all very well, but practical knowledge is much better, and I assert that if the candidate keeps his senses about him, understanding each question before he rushes at it, and by his conduct and answers convinces the court that he is a practical man, he will pass like a blaze of whins, no matter if he is ignorant of all the cruxes ever invented. *The examination is a fair one*, and if it ever falls into disrepute, the students may thank themselves for it in a great degree. Bah! Let the students learn any way they like, but let them not present themselves for letters testimonial until

they know and understand the grand profession they have wilfully engaged in; let them devote their days to work and their nights to sleep; let them avoid "the shades" to get a knowledge of midwifery; let them learn anatomy by using the scalpel; let them study disease while they can do so without being responsible for the treatment—and then when they do go in, they will find that grinders' tips contribute very little to a happy result.

I am now practising in the country, miles from any brother chip, and if I was depending on the cruxes I did learn at grind for any success I may have in practice, I would be as much mistaken as Doran was about the ass. Far be it from me to apply these remarks to all the students, as I know that there are many among them who, with industry and hard work, are yet to become bright ornaments of our glorious profession, and these are the very men who neither grumble nor make out grievances.—Believe me to be, my dear Sir, your humble servant,
WHIPCORD.

THE MEMORIAL OF THE IRISH MEDICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

MY DEAR SIR,—As the letter I had the honour to address to the General Council of Education and Registration, inclosing, as Chairman of the medical meeting held on the 28th of December last at the Limerick Junction, a resolution passed unanimously by the meeting has been under discussion and commented on in the proceedings of the Medical Council. I enclose you a copy of the letter, and request you will publish it in the next number of THE MEDICAL PRESS AND CIRCULAR, in order that it may be in the hands of the members of the Medical Association and of the profession generally in Ireland prior to the annual meeting of the Association on the 4th of June, when I trust the proceedings of the Medical Council will be *fairly, firmly, and moderately* discussed.—I am, dear Sir, yours very faithfully,

THOMAS L. MACKESY, M.D.,
President Irish Medical Association.

Saturday, May 26, 1866.

IRISH MEDICAL ASSOCIATION.

Royal College of Surgeons in Ireland, Feb. 12, 1866.

SIR,—As President of the Irish Medical Association and Chairman of a meeting of the Medical Profession in Ireland, I enclose a copy of a resolution passed unanimously.

The meeting, called on a requisition signed by about 270 Physicians and Surgeons, was held at the Limerick Junction on 28th December last, and was numerously attended.

Together with the resolution to which I wish to draw the attention of the Medical Council, I beg to enclose a copy of my address on the occasion, and to request you will submit both papers to the General Council of Medical Education and Registration of the United Kingdom.

In a letter I have recently received from an influential member of the Medical Council, the writer, in referring to my address, says:—"You have fallen into a mistake on the first page in complaining that the Council had not drawn up and enforced on the different medical bodies empowered under their respective charters; &c. &c., uniform system, &c. &c. The Medical Council has no power to enforce any course of study or examination. They tried it with the University of Edinburgh, in the second year of their existence, and were beaten. The several Corporations may do as they like, and in the present state of free trade and under selling one another for the profits of diplomas, I see no hope of any amendment.

Under such circumstances, I trust the General Council will no longer delay in making application to Parliament for an amended bill, granting to the Council full power to enforce a uniform system of preliminary and medical education on all medical bodies chartered and empowered to grant diplomas or licences in medicine and surgery. I believe the Council would be supported in this application by every medical practitioner in the United Kingdom who has at heart the true interest of the public and the honour of our profession, as the present state of free trade and under-selling for the profit of diplomas is injurious to the com-

munity at large, and lowering to the *status* and character of medicine and surgery. Medical registration can be of no advantage if it does not guarantee that the legally registered physician and surgeon has been regularly educated and fully competent to discharge the responsible duties of his profession.—I have the honour to be, Sir, your most obedient servant,
THOMAS L. MACKESY, M.D., Chairman.

To Dr. F. Hawkins, Registrar.

THE COUNCIL OF THE COLLEGE OF SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.
SIR,—In common with other Fellows in my neighbourhood, I was rejoiced to see that Dr. Mapother was seeking a seat on the Council. While his exertions during his connexion with the educational department of the College for the last twelve years has rendered him one of the most popular teachers in this country, his writings have gained him even a larger reputation. His energy would render him a most useful member of the Council, and, if I mistake not, he will be one of its most punctual members.

The profession owes him much for his advocacy of public health matters and the comprehensive Act on the subject, which the Government has promised, was obtained by his showing them its pressing necessity throughout Ireland.

With regard to the admission of candidates for Fellowship without examination (a subject on which I have previously addressed you), I feel sure he would give it his most vigorous opposition. I was also gratified to learn that a provincial surgeon of eminence (Dr. Johnson of Kilkenny) was also a candidate for a seat, and if he has made arrangements so that he will be enabled to attend a fair proportion of its meetings, his presence in the governing body will be of signal advantage.

I will conclude by expressing an earnest hope that the system of voting by proxy will be soon adopted by the College, so as allow Fellows residing at a distance to take part in the elections.—I am, &c. &c.,

H. R. HADDEN, M.D., F.R.C.S.

Clonakilty, May 26, 1866.

ROYAL COLLEGE OF SURGEONS, EDINBURGH AND UNIVERSITY REPRESENTATION.

At a meeting of this College, held yesterday, it was unanimously resolved to forward the following petition to Mr. Mr. McLaren for presentation in the House of Commons:—

"That your petitioners have learned with satisfaction that a bill has been introduced into Parliament whereby it is proposed to confer Parliamentary representation upon the Universities of Scotland.

"The Scottish Universities, which are four in number, have existed from very early times, and have always deservedly enjoyed the confidence of the public, as being the means of disseminating among them an education of the highest character. They possess a constituency considerably exceeding 4000, while the combined constituency of the University of London and the Queen's University in Ireland does not nearly reach that number; and to each of these Universities your petitioners rejoice to observe it is intended to give a representative.

"Your petitioners, in consideration of these circumstances, and that Oxford and Cambridge—the national Universities of England—and Dublin University, in Ireland, have each the privilege of returning two members to Parliament, would respectfully submit that the allocation of only one member for all the Scottish Universities is an inadequate representation for Scotland.

"Your petitioners believe that the allotment of two members instead of only one would be a much more equitable distribution, which would be hailed with greatly more satisfaction by the various Universities, and would also tend to enlarge the constituencies by the stimulus it would give to students taking honours in these Universities.

"For these and other reasons, your petitioners humbly beg that your Honourable House will take the premises into favourable consideration, and will be pleased to assign two representatives to the Scottish Universities.

"And your petitioners will ever pray.

"Signed, in name and by authority of the Royal College, by
"JAMES DUNSMURE, M.D., President."

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION,
1866.

— . .

WE published last week a copy of the Draft Amended Medical Bill sent from the Home Office to the Medical Council. The following is the Report of the Committee on the Bill :—

REPORT OF COMMITTEE ON THE DRAFT BILL OF THE HOME OFFICE FOR THE AMENDMENT OF THE MEDICAL ACTS.

The Committee beg leave to bring up their Report as it was finally adjusted by the Committee of the whole Council at their meeting of yesterday.

The Committee having fully considered the Bill and compared it with that which was drafted during the last Session of the General Medical Council, beg leave to submit the following Report :—

The Bill of the Home Office embraces substantially the Bill of the Council, with, however, some important additions and alterations which require specific notice.

THE PREAMBLE.—The Council's Draft Bill commenced with the following preamble: "Whereas the 'Medical Act, 1858,' has been found ineffectual to enable persons requiring medical aid to ascertain who are qualified practitioners," &c. This preamble the Home Office Draft leaves out.

The Committee are of opinion, that if there be no valid reasons against its being retained, it would be desirable that it should be restored as part of the proposed Bill.

2. THE REGISTRATION CLAUSES.—The object of the Clause as to Registration, proposed in the Council's Draft Bill, was to facilitate the duty of the Registrars in keeping their Registers correct; to enable persons who, having ceased to practise, may desire it to have their names erased from the Register; to render it imperative on the Registrar to address to any registered medical practitioner (instead of one letter within six months, as in the "Medical Act, 1858,") two letters within six months, at an interval of three months, inquiring as to change of residence, before erasing his name from the Register, and to prevent any person whose name has been once erased from the Register from being re-registered without the instruction of the General or Branch Councils.

In the Home Office Bill this Clause has been substantially adopted, though the phraseology has been somewhat varied, and the clause has been subdivided for convenience into eight Clauses. The Home Office Bill contains, however, two additions requiring mention—viz.:

1. The Council's Draft Bill provided, that when the name of any person shall have been erased from the Register by the General Council or any Branch Council, it shall not again be registered in any Register, except by direction of the Council which directed the erasure. The Home Office Bill adds the words, "or by order of a Court of competent jurisdiction." The Committee see no objection to this addition.

2. The Council in their Clause, has provided that the Registrar should address to any registered medical practitioner two letters within six months, at intervals of three months, inquiring as to whether he had ceased to practise, or had changed his residence, before erasing his name from the Register. The Home Office Clause diminishes still further the chance of any mistake, by providing that the letters to be addressed by the Registrar shall be registered letters; and that the second letter shall be addressed within fourteen days after the expiration of the first three months.

3. NEW CLAUSES AS TO REGISTRATION OF FOREIGN AND COLONIAL PRACTITIONERS.—The Home Office Bill embraces three new Clauses (XI., XII., XIII.), which

provides for the registration of foreign and colonial practitioners, under certain conditions, these conditions being (1.) That only those foreign and colonial diplomas and degrees shall be registered which have received the sanction of the General Medical Council, and shall be included in a new Schedule entitled Schedule (B), which the General Council have been requested by the Home Office to prepare.

(2.) That the provisions contained in Section XX., XXI., XXII. of the "Medical Act, 1858," shall apply to all qualifications contained in the Schedules to the proposed Bill; that is to say, that the Council, if they do not consider the course of study and examinations to be gone through in order to obtain any such qualifications sufficient, shall be entitled to represent the same to the Privy Council, who shall have power to suspend the right of registration.

(3.) That no qualification, whether British, Foreign, or Colonial, other than those included in Schedules (A) and (B) in the proposed Bill, shall be entitled to registration unless by order of the Privy Council, on the representation of the General Medical Council. (4.) That no person shall be registered upon any Foreign or Colonial diploma or degree who has not resided in the United Kingdom for a period of not less than twelve months immediately previous to making his application for registration.

The Council are aware, that though there was power in the Council to register, if they saw fit, persons holding only foreign or colonial diplomas and degrees—provided they had obtained them previously to the passing of the "Medical Act, 1858,"—yet that they had no power to register any such diplomas and degrees obtained after the passing of that Act. The Committee consider it fair and right that some provision should be made for the registration of foreign and colonial diplomas and degrees (especially if registration be rendered indispensable for practice under recognized medical titles), as it would be a harsh measure to deny the privilege of registration in this country to persons who may come from abroad or from the colonies holding foreign or colonial diplomas or degrees, provided these qualify for practice in the countries where they have been granted, and are deemed deserving of recognition by the General Medical Council, as implying Education and examination not inferior to the minimum required in the case of qualifications granted in the United Kingdom.

In the Home Office Bill a new Schedule (B) is proposed to be introduced, for the purpose of including those foreign and colonial degrees and diplomas which are to qualify for registration. The duty of preparing this Schedule has, as already stated, been committed to the Council by the Home Office.

Whilst the Committee have done their utmost to meet the wishes of the Government in framing a Schedule (B), they have found the difficulty of the task to be so great that they consider it preferable to make a provision in Clause XII. of the proposed Bill, by virtue of which it shall be lawful for the General Medical Council annually to prepare and submit to the Privy Council, for approval, a list of those foreign and colonial qualifications which, from time to time, the General Medical Council may consider worthy of recognition—this list to be published in the *London Gazette*.

4. REGISTRATION OF THE DEGREE OF BACHELOR OF SURGERY.—The Committee see no reason that the degree of Bachelor of Surgery, conferred by any University in the United Kingdom, which now is, or hereafter shall be, legally entitled to confer the same, should not be included in Schedule (A).

5. THE PENALTY CLAUSE.—This important clause, as framed by the General Council last year, has been substantially adopted in the Home Office Bill. There is only one important point requiring notice—viz. that instead of the word "Doctor," as in the Council's Draft Bill, the words "Doctor of Medicine" have been used in the Home Office Draft Bill. The Committee believe that the effect of this alteration is materially to weaken the clause; as, if it be retained, unqualified persons will continue as now to

practise Medicine, calling themselves "Doctors," but not "Doctors of Medicine," and will thus evade the penalties. It might be said that by using the word "Doctor" only you include all Doctors, whether of Philosophy, Law, &c. The answer to this is, that it is only those who, not being registered, are "practising medicine under the title of Doctor," who are affected by the Clause. The Committee would advise the Council to represent this matter very specially to the Home Office.

The Committee believe that the Home Office Bill, with the amendments suggested by them to be adopted by the Council, would prove a desirable amendment of the Medical Act, one calculated to benefit the medical profession, and the public, for whose protection from unqualified practitioners it makes more efficient provision. They therefore trust that the Council will adopt it, and will, before the conclusion of the present Session, send a deputation to the Home Office to state the views of the Council regarding the Bill; and further, to urge on the Government the expediency of the Bill being introduced as a Government measure."

ANDREW WOOD, Chairman.

The Committee have carefully gone over, with Mr. Ouvry, the Draft Bill, with the alterations adopted by the Committee of the whole Council. They beg leave to make the following suggestions in reference to the Bill as it now stands:—

"1. The Committee recommend, that as Clause XI., as originally adopted by the Council, is inconsistent with Clauses XI. and XII., as subsequently agreed to by the Committee of the whole Council, the first mentioned Clause XI. be omitted from the Draft Bill.

"2. The Committee recommend, with a view of simplifying the language of the Clause adopted in place of Clause XI. by the Committee of the whole Council, that these words should be erased—viz.: 'of such qualifications as shall from time to time appear to the General Medical Council as proper to be included in the list;' and that the words 'General Medical Council' should be substituted for 'such Council.'

"3. The Committee recommend, that in lieu of the third division of Clause XI. of the Home Office Draft Bill, it be provided in Clause XIII. that Sections XXIX. and XXXIX. of the 'Medical Act of 1858' be added, so as to bring persons registered under foreign and colonial qualifications under the same liability of removal from the Register, for offences, as those registered under Schedule (A) to the Medical Act."

The Committee then submit for consideration of the Council a copy of the Bill with the Amendments above suggested.

The following are the reasons of the General Medical Council for suggested alterations in the Draft Bill to amend the Acts relating to Practitioners in Medicine and Surgery:—

"PREAMBLE.—In the Draft Bill prepared by the Home Office the Preamble suggested by the Council has been omitted. The Council would submit, that it is desirable to state the grounds on which fresh legislation is thought necessary, and, therefore, that the Preamble, either in the form suggested by the Council, or in any more apt words, should be adopted.

"CLAUSE X.—The Clause, as framed by the Home Office, is considered open to objection, inasmuch as it would give to the Registrar power to erase from the Register the names of gentlemen who have ceased to practise, although such gentlemen may wish to retain their names on the Register. This is not desired; the main object of the Clause is to enable the Registrar to remove the names of persons who have really ceased to practise and whose addresses are not known. This will be effected by the proposed mode of sending letters, and the Council therefore have suggested a slight alteration in the Clause in accordance with this view.

"CLAUSES XI. & XII.—The Council have ventured to suggest a modification of these Clauses. The main feature of the alteration is the doing away with the pro-

posed Schedule (B) to the Act. The Council has done its utmost to meet the wishes of the Government in framing such Schedule, but they have found the difficulty of the task to be so great, that they have ventured to propose that the list of bodies, whose diplomas shall confer a qualification, shall be inserted in a list to be annually prepared by the General Medical Council and submitted to the Privy Council. By this means the General Medical Council will have the opportunity, from time to time, of making inquiries as to the status of the several foreign and colonial bodies, the nature and extent of their studies, and the quality of their examination, so as to judge whether they are worthy of recognition in the proposed list.

"It has appeared to the Council that the third provision of Clause XI, which authorizes the Registrar to refuse to register any person who shall have been guilty of an offence which would prohibit him from practising in his own country, is open to objection on several grounds: 1st. It would cast a judicial responsibility on the Registrars, which, by the 29th Section of the 'Medical Act, 1858,' is given only to the General Council. 2nd. The terms of the Clauses might be considered to cover offences which, although they might disqualify the practitioner from practising in his own country, would not be considered as an objection to his practising in this country, offences, for instance, of a political nature, or otherwise, not involving moral guilt. On these grounds the Council considers it safer to leave foreign practitioners in the same position as the practitioners of the United Kingdom, by making them amenable to the Sections XXIX. and XXXIX., of the 'Medical Act, 1858.'

"CLAUSE XIII.—The Council proposes to amend this Section, so as to bring Clauses XXIX. and XXXIX. of the 'Medical Act, 1858,' within its operation.

"The Council is aware that the proposed addition to this Clause does not fully meet a difficulty which the Draft Bill prepared by the Home Office was intended to meet, inasmuch as there is no power to remove from the Register the name of any colonial or foreign practitioner who may, in his own country, have been convicted of any crime or offence.

"The Council has failed to perceive any means in which this difficulty can be effectually met, owing partly to the difficulty of obtaining evidence of any such conviction, and the further difficulty of defining the class of offences which ought to exclude from the Register.

"The Council would be very glad if the advisers of the Government could suggest a clause adapted to the case.

"CLAUSE XIV.—The Council consider it would be expedient not to limit this Clause to the London University, but to extend it to any University in the United Kingdom which now is, or hereafter shall be, legally entitled to confer the degree of Bachelor of Surgery.

"CLAUSE XVI.—The Council proposes to amend this Clause by striking out the reference to the proposed Schedule (B) to the Act, and by striking out the words 'of medicine' after the word 'Doctor.' It is to be observed that the taking of the title of 'Doctor of Medicine' is prohibited by the earlier part of the Clause, inasmuch as it is one of the designations enumerated in Schedule (A) to the 'Medical Act, 1858.' Its subsequent introduction, therefore, is wholly unnecessary, whereas the introduction of the title 'Doctor' simply is all important to the efficiency of the operation of the Clause. The title 'Doctor' is the one most commonly assumed by unqualified persons practising medicine; and if such practice be allowed to continue, it is obvious that any unqualified person, by assuming that designation, might evade the penalty of the Clause. If it be said, by using the word 'Doctor' only in the Clause, all doctors, whether of philosophy, law, &c., are included, the answer is that the Clause applies only to those who, not being registered, are practising medicine under the title of Doctor. The Council beg to submit a print of the Bill amended in accordance with the above suggestions."

STR.—The Draft Bill framed by the Home Office for the

Amendment of the Medical Acts has been very carefully considered by the General Medical Council, and, at the request of the Council, I have the honour to transmit herewith a print of the Bill framed by the Home Office, with such amendments therein as appear to the Council advisable.

I have also the honour to transmit a statement of the reasons which have induced the Council to suggest the amendments; and I am to ask that you will, at your earliest convenience, be pleased to receive a deputation from the Council, to consider the amendments in question.—I have the honour to be, Sir, your most obedient, humble servant.

The Right Hon. Sir George Grey, Bart., &c. &c.,
Home Office.

THURSDAY, MAY 24TH.

Dr. ANDREW WOOD, as Chairman of the Committee on Medical Acts Amendment Bill, brought up the Report of that Committee, and suggested, that as several verbal alterations had been made, each Clause should, for the more effectual mode of placing it before the Council, be read and considered *seriatim*.

Dr. STORRAR ruled that the Report must of necessity be read in its complete form.

With reference to Clause XII. of the Amended Bill,

Dr. PAGET said it was a very serious matter they had in hand, their solicitor (Mr. Ouvry) had propounded the law to them in the case of registering applicants who had diplomas of foreign or colonial universities, colleges, or any licensing bodies. He conceived that if the bill passed in its present form it would be a manifest injustice to British subjects: that the Council should be able in case of misdemeanour or misconduct in a professional sense, to bring this Act to bear upon, and to prosecute them for, it might be, a minor offence; whilst any man who, through a much graver one—political, social, or moral—was compelled to fly his country, might come over here, produce a foreign diploma, obtained we know not how, if he merely had resided in the United Kingdom twelve months, we dared not refuse to register him, because there was no clause in our Medical Act whereby we might first determine what the offence was with which in his own country he was charged—it might be of the vilest description—on which we might ground our refusal. This would, he repeated, be very unjust to the British subject, and would be lowering the standard of the profession by opening our doors to any foreign adventurer, telling him if he came to England we would give him the licence to practise—denied to our own brethren—would, in fact, sanction men who ought to be scouted by every professedly respectable practitioner.

Mr. CÆSAR HAWKINS then said, with the permission of the President, he would read a resolution he had framed, which he hoped would meet the requirements of the case. It was as follows:—

“That a new Clause be drawn up, or some words added by Mr. Ouvry, to a Clause like Clause 29 of the Act of 1858, which shall apply to persons registered under Clause 12 of the Draft Act on Foreign or Colonial qualifications, for crimes and offences committed in their own countries, of the same nature as those referred to in Clause 29 of the Act (1858), when committed in England, Scotland, or Ireland, by persons registered under the Act of 1858.”

This was seconded by Dr. PAGET.

The motion was negatived.

Dr. ANDREW WOOD then proposed, seconded by Dr. PARKES, “That the Report as amended be adopted.”

Amendment moved by Sir DOMINIC CORRIGAN, seconded by Mr. RUMSEY:—

“That the Secretary of State be requested to take the necessary steps to procure the issuing of a Royal Commission to inquire into the working of the Medical Acts, and to examine the Members of the Medical Council, and such other persons as they may see fit, with the view of framing a report that may lay the ground for a Medical Bill that will ensure the better education of candidates for the practice of the medical profession, and better protection for the rights

of qualified practitioners than the present Medical Acts afford.”

Sir D. CORRIGAN observed that he was indebted to the President for the very clear and succinct way in which he explained the full scope of the proposed Bill—viz., that the whole value to be gained by the Bill was the hope that “Doctor” simply would be substituted by the Government for “Doctor of Medicine,” and that the question was whether it would not be well to forego all opposition to the objectionable parts of the Bill to gain this great boon. If he had in the slightest degree misrepresented the President’s view he would feel obliged for correction. If otherwise, he might assume that he had correctly interpreted the President’s explanation of the proposed Bill. [The President assented.] He had now no hesitation in saying that it was a mischievous Bill, injurious to the profession and likely to be badly received by the public, and to lower both the profession and the Council in the eyes of the public. It professed to be a Bill for the protection of the profession, yet it actually repealed the most important and protective clause of the Medical Act of 1858. In the Act of 1858, cl. 34, provides that “the words ‘legally qualified Medical Practitioner’ or ‘duly qualified Medical Practitioner,’ or any words importing, or person recognized by law as a medical practitioner or member of the medical profession, when used in any Act of Parliament, shall be construed to mean a person registered under this Act.” But Clause 10 of proposed Bill, enacts, that “a person whose name has been erased from the register with his consent, on the ground of his having ceased to practise, shall not be liable to any penalty under this section by reason of his being engaged gratuitously in the cure or treatment of any disease or injury.” Now, mark the effect of this clause. A man obtains a diploma from some foreign College or University, it may be from some one of the thousand Universities of America, Germany, Italy, &c.—he gets his name on the register, then removes it, settles any where in the United Kingdom, and under this new Bill continues authorized to practise under this new proposed clause, free from all pains and penalties, from all control, may be guilty of “infamous” conduct in the language of the Act of 1858, and yet neither law nor General Council can interfere with him unless it can be proved that he has been paid for his attendance in the particular case in which an action may be attempted. Who is to be prosecutor in this action? Not the Medical Council, for it has already over and over again declined to prosecute. How is the payment to be proved? Only by the patient. Is that evidence likely to be had, or if the defendant deny the payment, which is to be believed? The ungrateful patient or the persecuted defendant as the counsel will put it. And this is called a Bill for the protection of “duly qualified practitioners.” Again, it is proposed in the new Bill that the Council shall have power to admit to registry the graduates of all foreign Colleges and Universities they may see fit, publishing an annual list of such. Of the extent of abuse to which this might be carried we may readily judge. Much has been said of the great value of the “Visitation of Examinations,” of its great necessity to insure that our licensing bodies conduct their examinations efficiently; but this proposed Bill empowers the Council to admit foreign graduates from all parts of the world without having the power to visit their examinations, and without the means of carrying out “a visitation,” even if the laws of other countries permitted it. In fact, it would place the diplomas of foreign countries in character and in advantage over our own. The law of 1858 permitted, and perhaps properly, that foreign graduates practising in the United Kingdom previously to the passing of that act should be registered. That was a fair protection for vested rights; but the act properly provided that there should be no registry of foreign diplomas after that date, thus obliging any foreign graduate after that date to pass an examination before one of our nineteen licensing bodies before being entitled to register. The proposed repeal of this protective and salutary law is called a Bill for the

protection of our own "duly qualified practitioners," and this is what the profession is now to get in return for £62,000 which they have paid into the funds of this Council. Were the Bill unobjectionable in every respect, it would be most injudicious to proceed with in the manner proposed. The Secretary of State has declined to take charge of the Bill to introduce it as a Government measure, and has told you in his letter on our minutes of 17th inst., "to find some one to take charge of it." Suppose the Council act on that advice, as they seem disposed to do, in what a humiliating position is it placed, obliged to court the patronage of every member on one side, with homœopaths and quacks of all kinds on the other side, like competing jobbing companies, the Government standing by indifferent. Will our President, or any member of our Council, put himself in such a humiliating position in the lobby of the House of Commons, with hat in hand, and

"Bated breath and whispering humbleness,"

to solicit votes? Better never go in for a Bill, but be content with the present, bad as it is, than run the chances that must occur of a Bill thus introduced coming out, as it most probably would, worse than our present Act. The two great wants are, as mentioned in the resolutions of the Medical Association of Ireland, and in Dr. Mackesy's letter, and embodied in the amendment now before us—"The better education of candidates for the practice of the medical profession, and better protection for the rights of qualified practitioners than the present Medical Acts afford." How far better protection is afforded by the proposed Bill has already been noticed. But suppose the Bill did ensure better protection or more stringent rules against unqualified practitioners, will the Legislature or the public for a moment countenance a Bill that asks for increased protection, for more stringent monopoly, as they would designate it, but takes no step whatever in this amended Bill for better education. They will naturally and not unreasonably say, "First show that you have improved education so as that all the candidates passed and if your several licensing bodies are fairly educated, then ask for increased protection, and you shall have it." Now suppose, as will be sure to happen, that some member stands up and reads this paragraph from the last report of the Navy Board, as to the education of the graduates or licentiates from our several licensing bodies who have come before them as candidates for medical service in the navy:—"The majority of those rejected were utterly ignorant of the Latin language, two failed altogether in anatomy and surgery, and two were so ignorant of *materia medica* that it would have been dangerous to have passed them as qualified." We are sorry to have to add that many of the manuscripts sent in the candidates have given evidence of such an ignorance of orthography and of the most ordinary rules of English grammar and composition as could hardly have been credited in members of a liberal profession." (*Vide* minutes of General Medical Council of Friday, May 18), and say to the House—"The men thus tested and pronounced ignorant of every knowledge requisite for the practice of medicine are at this moment practising, or are authorized to practise in private, and to take charge of our poor in public appointments, under the licenses of the Corporations whose representatives constitute the Medical Council, and with this evidence of their carelessness or corruption, they ask for increased protection. Those who are thus described by the Navy Board must have many like them throughout the country, and, as it now appears, unregistered practitioners cannot be worse than such registered men, it becomes a matter of indifference to us whether we are to be in the hands of registered or unregistered men. If the Council have not the power to enforce a better education and examination, then their first duty was to seek for it. If they have the power, then their fault is aggravated, and if the reports of 1865 from the Navy Board be referred to, it will be found

that in place of improving the state of education in candidates passed by several of our licensing bodies is worse in 1866 than it was in 1865. Sir D. expressed his own belief that the Council had no power, and quoted the following extract from a communication of his to Dr. Mackesy, Chairman of the Medical Association, quoted by Dr. Mackesy in a letter to the Medical Association, which letter was refused insertion on the minutes:—

"You have fallen into a mistake in the first page, in complaining that the Council had not drawn up and enforced on the different medical bodies empowered under their respective charters, &c., a uniform system, &c. &c. The Medical Council has no power to enforce any course of study or examination. They tried it with the University of Edinburgh in the second year of their existence, and were beaten. The several Corporations may do as they like, and in the present state of free trade and underselling one another for the profit of diplomas, I see no hope of any amendment."

Sir DOMINIC continued—And they continue to do as they like. In the proceedings of the Scottish Branch Council of 12th January, 1866, it is stated that in all Scotland only sixty-eight students were entitled to registration, the whole of the medical students who, in November, 1865, had commenced their professional studies in the Universities of Glasgow and Aberdeen, and a number of the students in the Edinburgh University, having been permitted to commence their professional studies without passing or completing their preliminary examination. And this is followed by a declaration from the University of Glasgow, that "it has been thought inexpedient to adopt the plan of registration recommended by the General Medical Council, as in that University medical students are permitted, in certain cases, to enter upon their professional studies without passing an examination in general education. This is the present state of medical education. The London University has distinctly and positively told the General Medical Council it will not be bound by its decisions. Other bodies have treated its directions with silence, signifying something akin to contempt.

Sir DOMINIC proceeded to summarize his reasons for proposing the Royal Commission. That the Council is in this dilemma: that it has the power, or it has not, to enforce sufficient education; that if it has, it has not exerted that power for ensuring it, and that for eight years, year after year, the licensing bodies all represented on the Council are permitted to send out licentiates or graduates totally incompetent for the practice of their profession. That if it have not, it should, in a proposed bill apply for the two joint objects required—viz., "better education" for the sake of the public, and "better protection" for the members of the profession. That, by applying for a Royal Commission, the Council will place itself in the honourable position of desiring to conceal nothing; of explaining all the defects of the present acts; of showing that the Council is desirous of attaining the two objects desired; of freely acknowledging its own shortcomings, if any, and with the assistance of the knowledge of the profession from without, laying before that Royal Commission such an amount of information as will lay the foundation for a bill as perfect as it can be made, and which, with such a foundation, Government will not hesitate to adopt.

He concluded by observing:—But suppose the Government say we will neither take charge of the present bill nor accede to your request to issue a Royal Commission, as proposed in the amendment, then the Council comes out blameless. Its duty will then be to do the best it can with its present Act, and to all future charges brought against it as to education or protection, it can reply—We asked the Government to inquire and to assist us, and they refused.

Mr. RUMSEY, in seconding the amendment, said he had long had the subject of medical education under reflection, and although he supported the amendment he did not think

it met the requirements in many particulars; he, nevertheless, was favourably disposed to a Royal Commission being appointed; it was a step in the right direction, and might eventually be productive of much good. He quoted an extract from a letter written by a very great authority to another equally learned in the profession, but whose names he would not mention, "that he but shared in the common opinion—with reference to the proceedings of the Council—that if the General Medical Council were to adjourn for very much longer periods than they do the loss to the profession would indeed be very small."

The PRESIDENT thought if Mr. Rumsey gave the names of the authorities from which he quoted it might give additional weight, in which suggestion Dr. Andrew Wood concurred, as such a slur upon the character of the Council ought not to be made unless substantiated by the authority of the writer.

Mr. RUMSEY said he could not do that, but he was happy to say he did not endorse this opinion, but merely quoted the paragraph in question that the Council might know what opinion was formed outside their pale, and act accordingly. He considered much good had been done by the Council, but there were points, and many of them so complicated, that no legislation could possibly remedy. The question was, whether the machinery in the Royal Commission so devised was adequate to the requirements of the profession. He thought not, but would express his satisfaction at the advance proposed to be made, though it was but a small measure.

Mr. HARGRAVE said he could not support Sir Dominic Corrigan's amendment for a Royal Commission, considering that he was either utterly inattentive to the working of the Medical Act or ignored its results. Two or three times during this meeting he alluded to the character of the Naval Surgeons in a most marked manner, specifying their ignorance of Latin, English, anatomy, surgery, and *materia medica*. The fact is, it is the dross of the medical students who now seek for admission into that service; no candidate well educated, of a good family and gentle blood, and two or three and twenty years of age, will enter it, or submit to the overbearing character of the captains; and the medical service in the navy is fast returning to the times of Roderick Random. Good medical candidates will not present themselves for the navy till the captains change their bearing and conduct to their medical officers. He further observed that the Government would grant no Royal Commission, as the Council failed in its duty in carrying out the provisions of the Medical Act, particularly Clauses XX. and XXI., which granted to the Council full powers of appeal to the Privy Council. The Medical Council was deficient in action and independence in not long since having availed itself of their valuable privilege to control recusant parties. He well recollected when first he had a seat in the Council there was a motion brought forward bearing on the College of Surgeons of England, which had declined to accede to some of the recommendations, to appeal to the Privy Council. The motion was lost by the casting vote of the then President, Sir Dominic voting with the party to which the President gave his two votes. He (Mr. Hargrave) visited the examination for the Master in Surgery in the University of Dublin last December, and was much gratified to be able to judge for himself, as he had heard so many conflicting and contradictory opinions as to the manner in which it was conducted. His visitation afforded him no little satisfaction and experience. The report of his visitation is now before the Council, and will speak for itself. In conclusion, he believed that no Royal Commission would be granted, as the Medical Bill gives the Council full powers, by appeal to the Privy Council, to remedy any shortcomings, whether of Universities, Colleges, or individuals, and thus bring the profession into harmonious working order.

Dr. ACLAND said, when a member of the Council made such a proposition and enforced it with such a speech as they had heard from Sir Dominic Corrigan, he confessed

that, considering the great length of time constantly given to discussions in that room, it would be most unseemly that they should hurry over this question. It was the last weapon he would put into the possession of Sir Dominic Corrigan of going out of the Council, and saying, that when he seriously brought forward a motion of this kind, they declined to entertain it, and finally shelved it altogether; and he would ask every member of the Council, whether they might not—had it not been for the course adopted by Sir Dominic in full right—he did not doubt the right, but the reason of it—whether the three days spent upon this Act might not have been spared if Sir Dominic had had the straightforwardness to inform them beforehand that it was his intention after three days' deliberation to pull them up to a dead-stand by bringing forward his proposition. The Council would pardon him for frankly expressing his opinion, that the constitution of that body was extremely difficult to work, and as an executive almost impossible; but as they did not make the executive, the question was, whether they did each, according to his capacity, the utmost they could to make it work. He believed every individual member could honestly answer this question, that to the best of their abilities, they had consistently performed the parts assigned them; and with regard to the statement handed abroad, that they were each determined to put forward and defend his own particular interest, he would simply deny it (hear, hear). He could say, in reference to the University of Oxford, which he had the honour of representing, that nothing would sooner cause him to forfeit the confidence of his friends than if they believed he advocated their interests only to the prejudice of the public good. What was more insulting to their character as Englishmen, than that they should have it reported all over the country that the moving principle of the Council was self and self only. He should be very happy to see a Royal Commission appointed, although he did not consider it necessary or proper that the Council should ask for it. He would repeat that he had not the slightest objection to it, and if it could help them out of their difficulties, and enable them to do the duty imposed upon them any better, he for one should heartily welcome it. There were several things he considered prejudicial to the proper working of the Council. One thing was, and which he objected to in the first instance, that of the introduction of reporters by which their deliberations, being made public, were fettered. Another point was, that they had undertaken to settle the most delicate and intricate details of education in the short space of four or five days, amidst the pressure of other business. In his judgment it would be far easier to do it by a committee of three or four sitting during the interval between the sessions, who should bring up their report to the General Council. There was one thing he would like to remind Sir Dominic Corrigan of, and that was in regard to a statement he had been pleased to make, that the Council had done nothing. On the one hand, he told them they had no powers, and on the other, that the powers they had were not exercised. What had they done? A great deal. Had not the Pharmacopœia been completed? Had not an immense deal been done for education? Did Sir Dominic imagine all was to be done in a moment, because he chose to pull the strings and agitate? He repeated that Sir Dominic Corrigan had advanced what members of the Council knew to be untrue, and it was not right to throw broadcast over the country such allegations. He should like to be told what body had set itself determinedly to protect abuses and to keep them up? If such a body were represented there, let Sir Dominic say which it was, and let its representative answer whether or not it was the case. With regard to education, professional and non-professional, it was his belief that there had been since the passing of the Medical Act a sincere endeavour to pull up the education of the students, and to qualify every man according to what was practically possible. The Council had done as much as any body constituted in so heterogeneous a manner could have done in the same time.

Of course they would be chargeable if they did not take steps to make the wheels run smoothly, and this he considered would be accomplished by such important business being prepared during the interval of the sessions by standing Executive Committees. He greatly admired the ability of Sir D. Corrigan, who, if he failed in getting this Royal Commission, he hoped to find side by side with the rest of the Council, and with his great powers endeavouring harmoniously to exercise the powers they possessed in a calm and judicious manner, not talking, as he had done, about coalition, and other violent measures; but with a feeling of trust and confidence in his colleagues, and in the good intentions of the several bodies they were called upon to represent, seriously and truly under great difficulty ties to work the machinery they possessed (loud cheers).

Dr. STOKES stated that from an experience of forty years, first as President of the Dublin University, and, latterly, in the Royal College of Surgeons of Ireland, he thought nothing was more remarkable than the great advancement in education in the Irish Colleges. Since the year the question was first mooted in the Council, great attention was paid to professional studies, and students of the present day were very far in advance of what they were seven years ago. This was not his opinion only, but that of many who were in the best position to judge of the truth of his assertion. He could not, therefore, admit that medical education had retrograded.

Dr. ANDREW WOOD said—Dr. Acland, in his very able speech, remarked that he was opposed, in the first instance, to the admission of reporters at their deliberations. He (Dr. Wood), however, rejoiced that they were then present, and that the remarks made by that gentleman would go forth to the world as a type of that manliness of purpose and feeling, that straightforwardness to do their very utmost for the advancement of medical education, and the promotion of the interests of the profession, with which he was sure every Member in the Council was actuated, though they might not all be able to express it so elegantly as Dr. Acland had done. He, for one, felt the strictures often cast upon them by Sir Dominic Corrigan and other gentlemen, both in Council and out of it, were quite unfounded; and Sir Dominic never seemed to fancy he had done his duty until he pointed out a flaw in their proceedings, a wound, or a disease, as it were, and then sat down complacently, leaving them to seek and apply the remedy. Was this helping forward the deliberations of the Council, did such conduct as this, of which they were all cognizant, promote the harmony of their meetings? Nay, it had the very reverse effect, and Sir Dominic appeared to rejoice in having created the difficulties and then refused to help them out.

The amendment of Sir Dominic Corrigan having been lost by 19 to 3, Mr. Wood's motion was then put and carried by 16 to 6.—The meeting then adjourned.

FRIDAY, MAY 25TH.

The minutes of the preceding day having been read by the Registrar (Dr. Hawkins), the adjourned consideration of the report of the Committee on the subjects of education was resumed. A long discussion arose, in which Dr. Acland, Professor Syme, Sir Dominic Corrigan, Dr. Paget, Dr. Stokes, Dr. Christison, Mr. Cæsar Hawkins, Dr. Sharpey, Dr. Apjohn, Mr. Cooper, Dr. Storrar, and Dr. Alderson took part, as to whether natural philosophy, including mechanics, hydrostatics, and pneumatics, should not be transferred from the optional to the compulsory subjects; and it was finally moved by Dr. STOKES, seconded by Dr. STORRAR, and agreed to:—

“That Natural Philosophy, including Mechanics, Hydrostatics, and Pneumatics, be adopted as one of the Optional Subjects.”

After several minor clauses in the report had been considered and passed, it was

Moved by Dr. STOKES; and seconded by Dr. STORRAR: “That the concluding paragraph of the Report be adopted—viz.:

“The Education Committee having considered the letter

and resolution of the Irish Medical Association forwarded by Dr. Mackesy, and referred to them, recommend that the resolution be entered on the minutes. The Committee further recommend the forwarding this resolution of the Council to Dr. Mackesy.”

Amendment, moved by Dr. EMBLETON; and seconded by Dr. ALEXANDER WOOD.

“That the concluding paragraph of the report be not adopted; but that the Registrar be requested to acknowledge the receipt of Dr. Mackesy's letter, and the resolution of the Irish Medical Association, and to inform him that the subject of them has received the full consideration of the Council.”

The amendment was carried, and having been put as a substantive motion, was agreed to.

The next subject on the programme for consideration was the report of the Pharmacopœia Committee.

Dr. CHRISTISON moved the adoption of this report.

Dr. QUAIN begged to second the same.

Dr. AQUILA SMITH objected to one or two points in the report. It needed, in his opinion, some little modification.

Dr. SHARPEY also concurred with Dr. Smith. The latter clause in the report, as follows:—“The Committee beg to inform the Council that they have not hitherto found it necessary to make use of any portion of the funds placed at their disposal by order of the Council”—might be misconstrued, as they had quite sufficient funds in hand to pay any of the gentlemen who had given their time and attention to this important matter.

Dr. APJOHN rose and said, as the oldest member of the Committee, he had a few remarks to make. Dr. Apjohn, however, seemed to be suffering from a very severe hoarseness, and as his speech, which was not concluded on Friday, on its resumption on Saturday was still inaudible to our reporter, we are unable to give it to our readers. From what, however, could be gathered, he seemed to maintain that the *old Pharmacopœia* was still considered preferable to the new one, and adduced many facts to prove the assumption—that many of the most influential bodies in the United Kingdom still adhered to and dispensed from the old *Pharmacopœia*. He moved the following resolution, seconded by Dr. SMITH:—

“That it be an instruction to the Pharmacopœia Committee to give for each therapeutic compound of definite constitution occurring in the forthcoming edition of the *Pharmacopœia* two formulæ—the first being that in *ordinary use at present*; the second being the one constructed in accordance with the more recent views of what are called ‘Unitary Systems.’”

Dr. ANDREW WOOD said on looking over the old *Pharmacopœia*, he could not see how it was possible that either the student in chemistry or the chemist could adhere to the old *Pharmacopœia*, the old notation was anything but satisfactory, and he would suggest that the student should have both the old and the new form put into his hands, he would then see what differences there existed between them and form his judgment accordingly. He hoped the Council would, with a view to the advancement of scientific purposes, adopt the combination of both systems.

Dr. CHRISTISON said he was Chairman of the Pharmacopœia Committee, and from what had come under his notice in Scotland, the British *Pharmacopœia* had been everywhere hailed with pleasure. In Ireland also, he conceived from what he had seen and heard, it was very satisfactorily looked upon. It was only in England where it had been otherwise received, he knew there had been a good deal of opposition to the measure, and he knew there was a growing inclination to think very small of the doings of the Pharmacopœia Committee, but he maintained this opposition merely came from that body of practitioners who preferred the old system, because by these changes, which the Committee deem absolutely necessary for the perfection of the *Pharmacopœia*, these practitioners would be losers in a pecuniary point of view. The Committee of course were sorry for this.

He, however, believed the new Pharmacopœia would be generally acceptable. He was well aware the student did not base his knowledge in chemistry and pharmacy on the Pharmacopœia only, but he was not aware any chemist or practitioner ever used the chemical notations put forward by Dr. Apjohn; in fact he was almost certain they were never used at all. How could the Pharmacopœia Committee come to any other conclusion than the one they had. Why overload the Pharmacopœia with superfluous results of scientific experiments, why this proposition to introduce into its pages matter which would never be of any use either to the student or the chemist? He (Dr. Christison) sincerely hoped the Council had come to but one view on the subject, and that it would encourage the Committee by supporting the adoption of the report of the Pharmacopœia Committee.

The resolution of Dr. Apjohn having been put to the vote was carried by a large majority.

Several objections were raised against the adoption of one or two clauses in the report, and the debate on this important subject was adjourned.

REPORT OF THE DIRECTOR-GENERAL OF THE NAVY MEDICAL DEPARTMENT.

The following are the communications from the Director-General of the Medical Department of the Navy were read, with returns of the examinations of candidates, at the Medical Council.

Admiralty, W.C., Feb. 21st, 1866.

SIR,—With reference to your letter of the 27th of May, 1864, I have the honour to forward, for the information of the General Council of Medical Education and Registration of the United Kingdom, a report from the Board of Examiners on the examinations of candidates for medical commissions in the Royal Navy during the year 1865.

I have the honour to be, Sir,

Your very humble servant,

A. BRYSON, Director-General.

Dr. F. Hawkins,
Registrar of the General Council of Medical Education
and Registration of the United Kingdom,
32, Soho-square, W.

Admiralty, Somerset House, Feb. 14th, 1866.

SIR,—We have the honour to acquaint you, for the information of the General Council of Medical Education and Registration of the United Kingdom, that—

1. During the year 1865 twenty-one candidates presented themselves for examination for commissions as assistant-surgeons in the Royal Navy.

2. Of these four had been previously examined and rejected; and one underwent two examinations during the twelve months, having been unsuccessful on the first occasion.

3. Of the total number of candidates who presented themselves, twelve were successful and were admitted into her Majesty's service, and nine, having failed to satisfy us as to their professional knowledge, were rejected.

4. Of the twelve successful candidates, five passed good examinations, two moderately good examinations, and five indifferent examinations.

5. Of the five candidates who were twice examined, two passed good examinations on the second occasion, and three were again rejected.

6. The majority of those rejected were utterly ignorant of the Latin language, two failed altogether in anatomy and surgery, and two were so ignorant of materia medica that it would have been dangerous to have passed them as qualified.

7. The accompanying table supplies the information requested by the Medical Council with reference to the qualifications of the candidates, and the points on which they were chiefly deficient.

8. Appended to our letter to you of the 6th of March, 1865, reporting on the examination during the previous year, was a list of the subjects on which the candidates had at different times been examined, and which we stated, when put in the interrogative form, gave a fair idea of the general character of the questions put to the candidates. As the nature and scope of the examinations in no respect differed during the year 1865, we do not consider it necessary to forward another list herewith.

9. In renewing our expressions of regret that so much ignorance of the Latin language should be displayed by a large proportion of the candidates who submit themselves for examination, we are sorry to have to add that many of the manuscripts sent in by the candidates have given evidence of such an ignorance of orthography and of the most ordinary rules of English grammar and composition as could hardly have been credited in members of a liberal profession.

We have the honour to be, Sir,

Your obedient servants,

E. HILDITCH, Inspector-General.

JOHN SALMON, Deputy Inspector-General.

WM. R. SMART, Deputy Inspector-General.

ALEX. E. MACKAY, M.D., Deputy Inspector-General.

Dr. Bryson, C.B., F.R.S., &c., Director-General, &c.

Statement of the Qualifications, according to Schedule A, of the different Candidates who were examined for Medical Commissions in the Royal Navy in 1865, with the Results of the Examinations.

No. 1.—Lic. R. Coll. Phys. Lond., Mem. B. Coll. Surg. Eng. Passed an indifferent examination.

No. 2.—Lic. R. Coll. Phys. Edin., Lic. R. Coll. Surg. Edin. Rejected, 2nd exam. Latin examination bad; Anatomy indifferent; Surgery bad.

No. 3.—Mem. R. Coll. Surg. Eng., Lic. Soc. Apoth. Lond. Passed, 2nd exam. A good examination in all branches.

No. 4.—Mem. R. Coll. Surg. Eng., Lic. Soc. Apoth. Lond. Rejected, 2nd exam. Surgery only fair; deficient in all other branches excepting Anatomy.

No. 5.—Lic. R. Coll. Surg. Irel. Passed an indifferent examination.

No. 6.—M.B. Univ. Aberd., Mast. Surg. Univ. Aberd. Passed an indifferent examination.

No. 7.—Lic. R. Coll. Surg. Irel. Rejected. Utterly ignorant of Latin; Manuscript bad.

No. 8.—Lic. F. Phys. Surg. Glasg., M.D. Univ. Glasg. Passed a moderately good examination.

No. 9.—M.D. Univ. Aberd., Mast. Surg. Univ. Aberd. Passed a good examination in all branches.

No. 10.—Lic. R. Coll. Phys. Edin., Lic. R. Coll. Surg. Irel. Passed a moderately good examination.

No. 11.—Mem. R. Coll. Surg. Eng., Lic. Soc. Apoth. Lond. Passed an indifferent examination.

No. 12.—Mem. R. Coll. Surg. Eng., Lic. Soc. Apoth. Lond. Rejected, 2nd exam. Utterly ignorant of Latin.

No. 13.—Lic. F. Phys. Surg. Glasg. Rejected. Utterly ignorant of Latin; Manuscript bad.

No. 14.—Mem. R. Coll. Surg. Eng., Lic. Apoth. Hall. Dubl. Passed a good examination in all branches.

No. 15.—Lic. K. & Q. C. Phys. Irel., Lic. R. Coll. Surg. Irel., Lic. Mid. K. & Q. C. Phys. Irel. Rejected. Deficient in Anatomy, Surgery, and Latin; Manuscript indifferent.

No. 16.—Lic. R. Coll. Surg. Irel. Rejected. Utterly ignorant of Latin; Manuscript bad.

No. 17.—Mem. R. Coll. Surg. Eng. Rejected. 1st exam. Deficient in Chemistry, Materia Medica, Midwifery, and Botany. Passed, 2nd exam. A good examination in all branches excepting Surgery, which was fair.

No. 18.—Lic. R. Coll. Phys. Lond., Mem. R. Coll. Surg. Eng., Lic. Soc. Apoth. Lond., M.D. Univ. St. And. Passed an indifferent examination.

No. 19.—Mem. R. Coll. Surg. Eng., M.B. Univ. Edin. Passed a good examination.

No. 20.—Mem. R. Coll. Surg. Eng. Rejected. Utterly ignorant of Latin.

No. 21.—Lic. R. Coll. Surg. Irel., Lic. Apoth. Hall. Dubl. Rejected. Deficient in Chemistry, Materia Medica, Midwifery, and Botany.

~~~~~

THE GREAT NORTHERN HOSPITAL has recently received the patronage and support of Earl Russell, K. G., the Earl of Dartmouth, the Earl of Zetland, the Duchess of Newcastle, the Duchess of Gordon, Lady Taunton, and Lady Charlotte Denison. Two legacies have just been paid—viz., £300 (the late George Wheelhouse, Esq.), and £50 (J. W. White, Esq.); also £84 per J. Carr Jackson, Esq., the proceeds of a ball at Willis's Rooms; also £21 per J. W. Nevitt, Dramatic Club." A vigorous effort is being made to extend the benefits of the hospital, and to double the number of the beds, which are constantly filled.

Medical News.

TO THE PRESIDENT AND MEMBERS OF THE GENERAL MEDICAL COUNCIL OF THE UNITED KINGDOM.

THE MEMORIAL OF THE COUNTY AND CITY OF CORK MEDICAL PROTECTIVE ASSOCIATION

RESPECTFULLY SHOWETH—

That your Memorialists look forward with deep interest to the measure which they understand is likely soon to be introduced into Parliament to amend the Medical Act of 1858.

That this Act must be looked upon as having, up to the present time, fallen short of what was expected from it, in its two principal objects,—viz. :—The protection of the public, and a really improved system of medical education.

That with respect to the first of these objects, it appears to your Memorialists that Registration must continue to be all but nugatory, unless the new legislation render it imperative on the Council to order, through duly authorized officers, the prosecution of all persons incurring the penalty specified in Clause XL. of the Medical Act; or that which may be substituted for it.

That the vastly more important object of securing a sound and adequate education for all candidates for medical and surgical qualifications, is not, in the apprehension of your Memorialists, likely to be attained whilst the powers of the Council continue to be limited, as they are at present. To be enabled efficiently to provide for the country a body of properly qualified practitioners, it appears to Memorialists that the Council should be empowered to prescribe and enforce such educational regulations as may be found requisite for the attainment of that important object.

That no education, Memorialists respectfully submit, can be considered sound and adequate, which does not include, as preliminary to entering on medical studies, properly so-called, such a course both literary and scientific, as will enable the student effectively to master the varied subjects of professional study with which he will have to grapple, and afterwards to take such a position amongst men of general information, as will be calculated to maintain for medical science the estimation in which it is desirable, for the good of mankind, that it should be held.

That the course for a degree in arts in the different Universities, should, in the opinion of your Memorialists, be essential preliminary to that for a degree in medicine, and that a course of education, embodying both classical studies and the various branches of physical science, should be indispensable before entrance on medical and surgical education of whatsoever character.

Wherefore, your Memorialists would respectfully suggest the expediency of the Council seeking for such a modification of Clause XLI. of The Medical Act, as will secure the prosecution of offenders against its provisions. But especially of seeking for the power to establish a uniform curriculum of studies, preliminary and professional, which shall be binding on all the educational bodies of the country.

And your Memorialists, &c.

Notices to Correspondents.

- Medicus et Chirurgus.*—The letter is inserted.
- St. Bartholomew's Hospital.*—The report is inserted.
- The Harveian Society.*—The notice is inserted.
- "*Victim of Quackery.*"—The gentleman named is a duly qualified and registered practitioner.
- Mr. Harry Lobb.*—The papers have been received.

- Mr. Griffin.*—The letter has been received.

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following subscriptions have been further received on behalf of the above fund :—

|                                    |         |
|------------------------------------|---------|
| W. B. Irving, Esq., Newark (2nd)   | £0 1 0  |
| Thomas Robinson, Esq., Alton (2nd) | 0 5 0   |
| Henry J. Matthew, Esq., Horsham    | 0 10 0  |
| Amount previously announced        | 136 6 3 |
| Received at <i>Lancet</i> office   | 13 11 6 |

Yours obediently,  
145, Bishopsgate-street, London. ROBERT FOWLER, M.D.,  
Treasurer and Hon. Sec.

ERRATUM.—In Dr. Murney's paper on "Paralysis," page 538, second column, line twenty from the top, for *incessantly*, read *incapacity*.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 22nd inst. :—

- Adams, Edward John, Charlton, Kent.
- Archdall, Gordon, Bundoran, Co. Donegal.
- Birch, George, Kingsland.
- Carver, Charles Handasyde, Nottingham.
- Fair, Campbell, Outerrard, Co. Galway.
- Galton, John Charles, M.A. Oxon, Exeter.
- Horsfall, B.A. Oxon, Leeds.
- James, John Rees, Llanelly, Carmarthen.
- Johnson, David, Magherafelt, Co. Derry.
- Levy, Julius Lawrence, Westbourne-terrace.
- Lloyd, Thomas Franklin, Finsbury-circus.
- Morgan, Richard, Aberdare, South Wales.
- Murray, Berkeley, Barbadoes.
- Perry, Michael, Harwell, Berks.
- Pugh, David Roberts, Aberdovey.
- Sansome, Thomas, Birmingham.
- Schott, G. Friedrich Julius, M.D. Gottingen, Frankfort-on-the-Maine.
- Snee, Alfred Hutchinson, Finsbury-circus.
- Stevens, George Jesse Barnabas, Southgate-road.

The following were admitted members on the 23rd inst. :—

- Evans, Julian Augustus Michael, Pinuer.
- Mallock, Edward Cruikshank, M.D. McGill College, Montreal, Ottawa, Canada West.
- Parker, Leander Van Ess, M.D. New York, Nova Scotia.

It is stated that seven candidates for the Membership, out of the twenty-eight who offered themselves for examination, failed to acquit themselves the satisfaction of the Court, and were consequently referred back to their hospital studies for six months.

At the meeting on the 23rd, the under-mentioned gentlemen passed their examinations for full Surgeons in the Royal Navy :—

- Middleton, James, M.D. & L.R.C.S. Ed. (1860), Royal Hospital, Greenwich.
- Pickthorne, George Russell, M.D. Aberdeen (1862), H.M.S. Challenger, Sheerness.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 17th inst. :—

- Bush, John, Dearden, Newcastle-on-Tyne.
- Evans, Arthur Griffith, Narberth, Pembrokeshire.
- Gell, Thomas Sylvester, Stafford.
- Macaulay, James Campbell, Leicester.
- Milward, James, Cardiff.
- Newsam, Alderson, Totness, Devon.
- Smith, Edward Robert, Duoley.

The following gentleman also on the same day passed his first examination :—

- Sanders, Richard Careless, London Hospital.

REMEDY FOR SEA SICKNESS.—In the absence of ice, try Richardson's ether vapour spray along spine. Ice is not always available.—L.R.C.S.I.

BIRTHS.

At Kilmoganny, county Kilkenny, the wife of W. B. Phelan, L.R.C.S., L.R.C.P., &c., Medical Officer Kilmoganny Dispensary, of a daughter, on the 19th of May.

DEATHS.

BRADSHAW.—On the 6th April, at Sierra Leone, Francis Bradshaw, Esq., L.R.C.S.I., L.R.C.P.E. Dr. Bradshaw served as Assistant Colonial Surgeon at Sierra Leone for over four years, and at the time of his lamented death was Acting Colonial Surgeon. For several months fever of a malignant type was epidemic in the Colony, and Dr. Bradshaw, at the early age of 28, fell a victim to his zeal and assiduity in the discharge of his arduous duties.

WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING MAY 26TH, 1866

"SALUS POPULI SUPREMA LEX."

Hospital Reports.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

RHEUMATIC FEVER; ALKALINE TREATMENT; NO CARDIAC COMPLICATION.

Case 1.—J. L., a boy aged 12 years, was admitted into the Whitworth Hospital on the 25th of April, 1866. He had been a week ill before admission. When seen after admission he was in great pain, all the principal joints being engaged. He was ordered a combination of the three salts of potash—viz., bicarbonate of potash, ℥ii.; acetate of potash, ℥i.; and ℥i. of nitrate of potash in the infusion of gentian. The joints were assiduously poulticed with a mash of chamomile flowers and poppy heads. Small doses of opium were given at frequent intervals to allay pain and promote sleep. This boy progressed most favourably, and defervescence took place with unusual rapidity, the swellings and pains in the joints subsided, and on the fifth day after admission he was quite convalescent. The heart was carefully examined each day, but no lesion of any kind became developed in it, and the patient was soon after discharged well.

Case 2.—W. R., male, aged 25, was admitted into the Whitworth Hospital on the 22nd of April. He had been ill for about a month prior to admission. When seen on the 23rd he complained of severe pains in the shoulders and elbow joints, and in succession all the principal joints and several of the minor ones of both hands became affected. Much pain was complained of, and the patient was sleepless. He was placed on a combination of the salts of potash, in the proportion of ℥iv. of the carbonate, and ℥ii. each of the nitrate and the acetate of potash in a bitter infusion. The joints were carefully poulticed with chamomile flowers and poppy heads, and quarter grain doses of opium were administered at intervals until sleep was procured. Severe suffering was complained of from time to time in the shoulders and elbows, for which a liniment composed of equal parts of lin. aconiti and lin. belladonnæ was employed with great advantage. This case progressed favourably, gradual amendment took place in all the symptoms, and he left hospital on the 11th of May, after a sojourn of nineteen days, perfectly well, and with the heart completely intact.

Case 3.—J. R. This patient, a male, aged 32, had been admitted to the Hardwicke Hospital on the 2nd of March, labouring under typhus fever of a severe and aggravated type. He was an inmate of that institution for seven weeks. On the 20th of April he was transferred to the Whitworth with well-marked symptoms of rheumatic fever. He now lies side by side with his namesake, the patient last named, and the two cases presented numerous points of similarity. They were treated on identically the same plan, the combination of the three salts of potash, poultices of chamomile flowers and poppy heads to the joints, opium at intervals to allay pain and procure sleep, and the occasional use of the combination of the aconite and belladonna liniments when pain of a severe degree was complained of. Convalescence was established in both about the same time, and both left hospital at the same period, and in both there was an entire freedom from cardiac complication.

Case 4.—J. G., æt. 36, a man of powerful frame, of great muscular energy, and a very free liver, was admitted to hospital on the 16th April. He was found labouring under an unusually severe form of rheumatic fever. The knees, ankles, and the wrists especially were excessively painful, and he was restless and sleepless. Poultices of chamomile flowers and poppy heads were placed upon all the joints; he was put on the combination of ℥ss. of carbonate of potash, ℥ii. each of the nitrate and acetate of potash, in infusion of calumba, with opium in quarter-grain doses at intervals, to induce sleep and allay pain. Under this treatment he progressed favourably until the 21st, when symptoms of a very unusual character developed themselves. There was much cerebral excitement, with tremor, illusions, attempts to get out of bed, and much violence threatened to those around. This condition lasted for five days and resisted all treatment, when, despairing of his recovery, his wife insisted on removing him from hospital, and he was brought home. In two days subsequently, however, he was again admitted to hospital, with persistence of the condition just described, and the rheumatic affection in *statu quo*.

Under the influence of a thirty-grain dose of capsicum, which, it may be mentioned, had proved ineffectual on two occasions previously, he was now rapidly restored to consciousness: all tremor, illusions, and violence subsided, and there remained the uncomplicated but very severe rheumatic condition to be dealt with. He was again placed on the combination of potash salts above mentioned; the joints were carefully poulticed as before, and he now began to exhibit signs of rapid amendment. The heart was carefully explored from day to day, but notwithstanding the excessive development of the rheumatic condition exhibited in his system, the frequent exposure, which was entailed by the condition of violence and delirium into which he had fallen, and further by his removal from hospital, this organ completely resisted all contamination, and he left hospital perfectly convalescent, and with a sound heart, about thirty-three days after his first admission.

In commenting on these cases, Dr. Lyons observed that they were too few in number to admit of any absolute deductions being drawn from them. Having, however, in many other instances employed like means with like results in the treatment of this disease, he confidently recommends it as one well worthy of consideration. The patients were in all cases carefully fed on farinaceous aliment with milk. Wine was occasionally allowed when the symptoms of the case demanded it. Much ease is experienced from the application of the poultices of chamomile and poppy-heads to the affected joints, the great secret being that they require to be applied hot and hot about every third hour, any chill to the joints being very injurious. In the combination of the salts of potash referred to will be found the alkali requisite to neutralize any excess of uric or other acid in the system, and in the diuretic salts is provided a stimulus to free elimination through the kidneys. The entire freedom from cardiac complication in the four cases cited is worthy of note.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

OPERATIONS PERFORMED IN THE MEATH HOSPITAL DURING THE MONTH OF MAY BY MR. COLLIS.

[Reported by ARTHUR WYNNE FOOT, M.D.]

MAY 1ST: For femoral hernia, on the right side, in a woman, 56 years of age. The hernia appeared for the first time on the 28th ult., since which time, until the date of operation, it continued strangulated. Gay's modification of Petit's operation was performed.

2nd: For complete dislocation of both bones of the right forearm backwards at the elbow, in a boy aged 15. The dislocation had occurred a month previously, and having been, in the first instance, treated by a bone-setter,

was now irreducible. Forceful flexion, under chloroform, was resorted to in order to restore motion in the joint, the forearm having been almost immovably fixed in a straight position. The operation was repeated with good effect on the 16th, and the present condition of the boy's arm is very good.

3rd: For femoral hernia on the right side of four years' existence, strangulated for six hours, in a man 48 years of age. Gay's modification of Petit's operation performed. He left hospital quite recovered on the 14th with a truss to prevent recurrence.

9th: For double harelip in a boy six and a half years of age; the intermaxillary bone was reduced and fastened in proper position by an iron wire. On the 6th of April this boy had been operated on for congenital fissure of the soft palate under chloroform; section of the muscles was performed, three points of horse-hair suture, one of fine silk, and one ligature of reserve of thread were used to approximate the vivified surfaces. All sutures were removed (except the anterior one of horse-hair) on the 28th, union being satisfactory. This case appears to be the first one of cleft palate operated upon at such an early age. The operation for harelip remains to be completed.

15th: For pannus of left eye in a man 31 years of age. Furnari's operation performed of circumcision and removal of circular ring of conjunctiva and enlarged vessels round cornea.

22nd: For depressed fracture of skull over the superior longitudinal sinus, much hæmorrhage, in a man aged 35. Removal of a half circle of bone in order to elevate the depressed fragment.

23rd: For necrosis of lower end of right femur, in a patient aged 12; disease of eighteen months' standing, the result of a fall from a donkey. Removal of a large sequestrum through an opening on the inner side of the thigh close to the joint.

29th: For vesico-vaginal fistula, aperture the size of No. 12 catheter, edges of the fistula split, four points of quilled suture and five of interrupted suture of horse-hair employed. Patient aged 31.

### ST. VINCENT'S HOSPITAL.

#### TREATMENT OF LARGE ABSCESSSES BY DRAINAGE.

##### Dr. O'FERRALL'S WARDS.

R. R., aged 19, by occupation a labourer, residing at Chapelized, was admitted to St. Vincent's Hospital on the 17th April, 1866, under the care of Dr. O'Ferrall. It appeared that on the previous March 17, he fell on his hip, and at once went to an hospital where he was treated for the injury. Some days previous to leaving hospital he complained of severe pain in the left shoulder, to which was applied a liniment, and was discharged. Three days after leaving the Hospital referred to he sought admission into St. Vincent's Hospital. At the time of his admission he was observed to have a large tumour situated on the left scapula extending backwards beyond the vertebral border, and engaging both supra and infra-spinous fossæ; the prominence of the spine being completely obliterated, and extending below and without as far as the lower margin of the latissimus dorsi. There was great increase in the breadth of the shoulder with an œdematous hard swelling occupying the outer portion of the supra-clavicular fossa. At the time of my first visit (22nd April) it could be felt to fluctuate, and it appeared that the patient had rigors twice since his admission, and experienced pain of a more or less acute character.

On the 26th April Dr. O'Ferrall inserted a drainage tube at about the level of the spine of the scapula, carrying it downwards to a little below the angle, when it emerged, and through it a considerable quantity of healthy pus was

discharged with great relief to the patient. The discharge gradually diminished.

The patient was treated with wine and bark, and when I last saw him on the 14th May, the tube had been withdrawn and the tumour had completely disappeared. At the same time it was noticed that the man's general health was much improved by his stay in the hospital. At no period was there an offensive odour from the pus. There was a slight movement of the tube made once each day to prevent the aperture becoming clogged, which necessarily gave him great pain when withdrawing the tube. Dr. O'Ferrall made use of a simple manœuvre—viz., firmly fixing the elastic tube between the forefinger and thumb of one hand, while withdrawing with the other hand the loose end; by this means the length of the tube is increased, while its calibre is diminished so as to enable the surgeon to draw it through its track without exciting the slightest pain; and if desirous of removing the tube, by suddenly letting go the end held between the finger and thumb, by its elasticity it passes with a sharp click through the track without giving the least pain.

*Remarks.*—Referring to the practice of drainage in large abscesses, Dr. O'Ferrall remarked that two facts of practical importance were illustrated by this case.

1st. That during the progress of treatment no offensive odour of any kind in the matter flowing through the tube could be detected. This he attributed to the perfect ventilation by the perforated tube and the constant escape of the pus as rapidly as it was formed, and before it would have time to undergo any change by decomposition.

2nd. The employment of a simple mode of withdrawing the tube without causing the pain which the least movement in the daily dressing of the part had previously occasioned. The tube is held at both extremities, and extended by traction so as to diminish its calibre to the smallest possible amount. One extremity is then suddenly let loose, and the tube is found to have escaped from the wound with a sharp click and without the production of pain.

### NOTE ON THE REACTIONS OF PURE CHLORATE OF QUININE.

By CHARLES R. C. TICHBORNE, F.C.S.L., &c.

HAVING been requested by Dr. Lyons to prepare him some pure chlorate of quinine, the author sends the following note with the impression that it may be of use to those medical men who wish to try its efficacy as a new febrifuge. The writer thought it also more desirable to do so from the fact that hitherto this curious quinine salt has not been an article of commerce, and from the circumstance that what would apparently be the most simple and efficacious method of procuring it, produces a product which contains only a trace of the chlorate.

The salt can, however, be made in a state approaching absolute purity from chlorate of barium. The writer therefore gives the characters and tests by which the salt can be recognized.

*Characters.*—Chlorate of quinine presents the characteristics of the other chlorates, only in a less marked degree. When crystallized from a watery solution it forms small mushroom-shaped masses, which, on examination, are found to consist of filiform snowy-white crystals radiating from a centre. Crystallized from a spirituous solution, it resembles more the ordinary salts of quinine in appearance. Heated gently upon a spatula, it gradually melts, and after a little time goes off with a vivid combustion, which, if the salt is dry, sometimes amounts to an explosion. A carbonaceous residue is left. Treated with hydrochloric acid and gently warmed, it evolves chlorine copiously, which may be recognized by its smell. On adding ammonia in excess to this mixture an emerald green colour is developed. It is very soluble in boiling water, but rather insoluble in cold. When pure, it crystallizes with diffi-

culty from this solution, but much more readily if it contains traces of any of the ordinary salts of quinine.

*Tests.*—Chlorate of quinine when dissolved in water and acidulated with diluted nitric acid, should give no precipitate with chloride of barium, and none, or only a faint opalescence, with nitrate of silver. It should give no precipitate with diluted sulphuric acid, and as regards the quinine, should, on precipitation with ammonia, &c., correspond to the requirements given under the head of "Quinæ Sulphas" in the British Pharmacopœia.

### ON THE TREATMENT, AND ABOVE ALL, THE PROPHYLACTIC ARREST OF ASIATIC CHOLERA.

By HENRY MacCORMAC, M.D.

I HAD the management of Asiatic cholera in the Belfast Hospital for the treatment of that fell disease in 1832. I also saw and treated, very many cases of the malady both in 1848 and during 1854. I was singularly successful in 1832. By means of well-ordered arrangements, the cases were constantly under my own observation or that of very able and effective assistants. Opium and calomel were freely resorted to. Artificial warmth was maintained when requisite. Stimuli, alcoholic and otherwise, were judiciously exhibited. Counter-irritation, by means of sinapisms and otherwise, applied to the epigastrium, were found useful in checking vomiting. And cold water, only taking care to give it in small quantities at a time, sometimes iced, was freely, and I believe most advantageously made use of. In a few instances approaching collapse was arrested by the stimulus of emetics of sulphate of zinc. But, generally speaking, collapse as well as secondary fever, which latter only prevailed when the weather grew cold, was found terribly intractable. It is worthy of remark that although well-fed persons were found less liable to contract cholera, yet when they did contract it, and especially when they sank into collapse, recovered less readily, and were less amenable in respect of their disease to treatment, than, comparatively speaking, were hard-working, poor, ill-fed persons. Individuals of the latter stamp when they rallied from collapse and the circulation returned, almost always recovered. Whereas, well-fed persons, in opulent circumstances, even when the pulse and circulation, along with animal heat returned, very often died. When diuresis in addition to these, however, was established, very few perished. But similar facts in respect of deaths and recoveries, comparing the rich and the poor together, have been repeatedly observed, not only with respect to cholera, but also typhus fever and plague. Many more poor persons, to be sure, are carried off by these devastating maladies. Nevertheless, as a general rule, man for man, and with like treatment, the poor recover far more readily than do the rich. Cholera, however, is a truly precarious and disastrous malady, and it is almost infinitely better to arrest it at the beginning than to have to combat it afterwards. And, if there be a therapeutic fact more certain than another, it is that our success in the treatment of Asiatic cholera will, *ceteris paribus*, be in the exact ratio of the recency of the treatment.

The truth of this statement was abundantly exemplified in the results of house-to-house visitations. In Glasgow, for example, after a system of house-to-house visitation, during cholera periods, had been once fairly organised, the mortality was surprisingly small. Cases of premonitory diarrhœa, for example, that, if neglected, would have run on to intractable and perhaps fatal cholera, were arrested by means of an opium pill and an opiate draught, with a mortality actually not exceeding one in 1,400. Nothing could be more astonishing or more entirely satisfactory. Nevertheless, numbers perished owing to neglect. The preliminary purging was either not checked at all, or having been partially checked recurred again, and not being again checked, eventuated in the fully-formed and fatal disease.

I proved the fact myself in very, very many instances. Going among the dying and the dead, I have asked those about—Do you purge?—Yes. Very well, open your mouth; whereupon I could throw into the mouth and command them then and there to swallow a good grain or so of opium twitched from a lump of soft opium, which I always carried in my pocket for the express purpose. At the same time, and from the same source, I would produce a bottle of laudanum or Battley, and give 20 or 30 drops of the solution in a little water, taking care to leave a like dose to be repeated at bedtime or sooner upon an emergency. I remember once being in a house where four poor women, pitiful to relate, were lying dead at one and the same time. The mortality, in many instances, was greatly enhanced, too, by the homicidal practice, which I am sorry to say was too much encouraged, of giving and even repeating draughts of castor oil. It was too bad.

During 1854, it was, that some alterations in the building taking place, and a communication subsisting with the infected town, the Belfast District Asylum for the Insane, to which I was and am visiting physician, was visited with cholera. It broke out with startling suddenness, and forty of the inmates very rapidly perished. Many of the inmates were very unfavourable subjects for the disease, and I began to fear for the whole establishment. Intimately convinced, however, of the infinite value of prevention, it occurred to me that if I could not only arrest, but anticipate the premonitory diarrhœa, I might also arrest the disease. I immediately had prepared some dilute sulphuric acid, of whose general efficacy in the treatment of choleraic diarrhœa I had had ample experience; without waiting for the preliminary diarrhœa, I say, I gave to every inmate in the establishment a daily dose of about a drachm of the dilute acid in peppermint water. The existing cases of the disease having run their course to death or recovery, *no other instance of the malady occurred*; and I had the unspeakable satisfaction, owing, as I am intimately convinced, to the prophylactic efficacy of the dilute acid, of witnessing the utter disappearance of the disease.

I would strongly recommend, and as strongly urge upon the attention of the profession, and indeed the general public, the advisability, coupled, however, in every case with every proper general sanitary precaution, of having recourse, with respect to the entire community, of the prophylactic efficacy of dilute sulphuric acid, and in the very manner in which I myself tested it. I firmly believe, ever and always neglecting no effective sanitary precaution, that it would make us virtually masters of the situation, and render the ravages of cholera, really and truly, a thing of the past.

### Abstracts of the Scientific Societies.

ASIATIC.—May 7.—The Right Hon. Viscount Strangford in the chair.—Dadabhai Naorojee, Esq., was elected a Resident Member. — The paper was by Dr. J. Muir, "On the Interpretation of the Vedas." After citing at length the opinions of the representatives of the different schools of Vedic interpretation on the subject under discussion, Dr. Muir proceeded to show by a selection of instances from Yaska's Nirukta and from Sayana's commentary the unsatisfactory character of the assistance which those works afford for explaining many of the most difficult passages of the hymns, and the consequent necessity which exists, that all the other available resources of philology should be called into requisition to supply their deficiencies. His object more, particularly was, to point out either, (1), that Yaska and Sayana are at variance with one another in regard to the sense of particular terms; or (2), that they have each given one or more alternative explanations of many words, and cannot therefore be supposed to have had in such cases any positive knowledge of the real signification; or (3), as regards Sayana, that he expounds numerous words differently in different places, and must therefore, in some of those instances at least, be held to have interpreted them wrongly. Though fully admitting that the Indian commentators have been of the utmost service in facilitat-

ing the comprehension of the Veda, the author stated it as the conclusion at which he had arrived, that there is no unusual or difficult word in the hymns in regard to which their authority should be received as final, unless it be supported by probability, by the context, or by parallel passages.

ROYAL SOCIETY OF LITERATURE.—May 2.—The Rev. M. E. C. Walcott in the chair.—Major-Gen. Tremenheere read a notice of a visit paid by him to the ruins of Ephesus during the spring of 1864, and described at some length the position and present state of some of the most remarkable monuments on that celebrated site. General Tremenheere stated that the whole plain over which these ruins are scattered is about three miles wide, and that the ancient aqueducts built by Caius Pollio, on which an inscription remains bearing his name, and the site of the ancient theatre, are well defined. Mr. Wood, our consul at Smyrna, was engaged on some excavations at Ephesus during the period of General Tremenheere's visit.—Mr. Walcott read a curious paper on the derivation of numerous English words occurring in miscellaneous mediæval works, founded in a great degree on Mr. J. Hunter's MS. Nominale, now in the MS. room of the British Museum. Mr. Walcott's paper included a classified list of the price of materials, fruits, and food; the names of fabrics, animals, and measures; remarkable derivations of surnames; with the early spelling of many common and obsolete words. Mr. Walcott added some interesting notes in illustration of the above matters from the wardrobe accounts, inventories and other documents in the Public Record Office.

ZOOLOGICAL.—May 8.—Dr. J. E. Gray, V.P., in the chair.—A communication was read from Mr. F. Pascoe, giving an account of a collection of Longicorn Coleoptera formed in the island of Perang, and on the adjoining main land. The total number of species in the collection was stated to be 208, of which no less than 118 were considered to be new to science.—Mr. J. Gould brought before the notice of the Society some interesting additions to the Avifauna of Australia, contained in a collection recently formed at Cape York by Mr. J. Jardine, late Commissioner of Crown Lands in that district. Some of these birds were of species new to science, others had not been previously known as existing in Australia.—Mr. A. G. Butler read a monograph of the Diurnal Lepidoptera of the genus *Euplæa*.—Mr. P. L. Sclater pointed out the characters of a new species of Accipiter from New Granada, proposed to be called *Accipiter ventralis*.—A communication was read from Dr. G. Hartlaub, giving an account of a new form of *Passerina* Birds from Madagascar, proposed to be called *Eroessa tenella*.—Dr. J. E. Gray read a notice of a new Bat from Angola, proposed to be called *Scotophilus Welwitschi*; also some notes on the skulls of the various forms of Delphinidæ represented in the collection of the British Museum.—Mr. Alfred Newton exhibited, from the collection of Mr. W. Borrer, a specimen of *Sylvia aquatica* of Latham, recently killed in England.

ENTOMOLOGICAL.—May 7.—The Chairman exhibited a singular conical nidus of a spider, and also two cases of the larva of a species of *Oiketiscus*, both from New South Wales.—Mr. Bond exhibited a remarkable female variety of *Cabera exanthemaria*, bred by the Rev. Mr. Horton, of Po-wick, near Worcester.—Mr. Stainton exhibited some beautiful drawings of the larvæ of a species of micro-lepidoptera, collected by him during a recent visit to the south of France.—Mr. Newman exhibited some dead larvæ of *Hepialus lupulinus*, remarkable as forming the pabulum of a fungus, probably a *Sphæria*, which completely occupied the interior of the animals, and sent out its mycelia in all directions through the skin.—Mr. E. L. Layard called the attention of the Society to the fearful ravages of a species of white ant in the island of St. Helena. The insect was introduced in timber about twenty years ago from the west coast of Africa, but only within the last ten years had its numbers become serious; he believed that unless some effective means could be found to check its ravages it would ere long be impossible to employ wood on the island for any purpose whatever; it was at present confined to James Town, which may truly be said to be devastated by it: the whole of the Cathedral is destroyed, the books of the public library are devoured, and it was noticed that the theological works were eaten first, which he (Mr. Layard) attributed to their being less consulted than most others, and the insects therefore less disturbed in their work of destruction. Everything in the

town made of wood was more or less injured; and in the Government stores it was found that the moist traces of these insects on the outside of tin cases caused very speedy corrosion of the metal, and enabled the insects to make their way in and devour the contents; damage to the extent of many thousand pounds had already been done, and any one who could suggest some effectual method of destroying this pest would confer a vast benefit on the inhabitants of St. Helena.

## EXPERIMENTS ON THE EFFECTS OF DIVISION OF THE OPTIC NERVES.

By Dr. BASILIUS ROSOW of St. Petersburg.

In Dr. Basilius Rosow's "Experiments on the Effects of Division of the Optic Nerve," the animals operated on were rabbits. The superior rectus was divided in the ordinary mode of operating for strabismus—the distal end of the tendon seized, and the eye rotated downwards. The retractor bulbi was then divided, and, finally, the optic nerve. The posterior ciliary vessels and nerves were uninjured. Scarcely any blood was lost. A few minutes after the operation the pupil was usually contracted and irregular; in a few instances it was unchanged in form and dimensions. Ophthalmoscopic observation showed the optic disc whiter than natural in some cases, in others with a round or oval dark-brown spot in the centre, especially when the section of the nerve was made close to the sclerotic. The retinal vessels were small in most cases, but sometimes only the arteries were constricted, and occasionally no change was apparent. The choroid and iris were always anæmic.

Twenty-four hours after the operation the cases could be divided into two groups, according to the appearances presented. A. In a few cases panophthalmitis set in, with œdema of lids, congestion of conjunctiva, and a characteristic diffuse, bluish-gray haziness of the cornea, completely obscuring the pupil and iris. Forty-eight hours after the operation the cloudiness of the cornea remained in *status quo*, but there was remarkable diminution of the tension of the globe. The epithelial layer of the cornea was undisturbed, but a discharge of pus began to take place from the conjunctiva. One rabbit was killed after three days, a second after five days, and a third after fifty-two. In the last case there was extreme atrophy of the eye.

On post-mortem examination the cornea in the first two cases was found to be greatly thickened, and this was effected in such a manner as to render the posterior surface strongly convex, whilst the curvature of the anterior surface was scarcely altered. The projection was so great as to fill the anterior chamber, and to press the iris and even the lens backwards. In the third case the membranes of Descemet was attached to the front of the iris. In the second and third cases there was complete absorption of the vitreous humour, so that the posterior surface of the lens was in contact with the retina.

B. In the second class of cases there was no inflammatory reaction set up. Twenty-four hours after, there was slight œdema of the upper lid; the pupil was much dilated; the papilla red, and not well defined. The retinal vessels normal, or the veins alone dilated. The brown discoloration when this was previously present, remained unchanged, and the circulation in the choroid and iris was undisturbed. In three to five days all signs of inflammation passed off, and the only difference between the sound eye and the one which had been operated on was the wider pupil of the latter. In six of these cases (one of which was examined as late as fifty-one days after), the ophthalmoscope showed indistinctness of outline in the reddened papilla, and in many cases dilatation of the veins.

Microscopic examination of the retina in two instances (twenty-fifth and thirty-ninth days after the operation), showed that the retina preserved its morphological elements unaltered to a surprising degree; many groups of nerve fibres appeared to have undergone fatty degeneration, whilst others only appear to be paler than natural.—*Brit. For. Med.-Chir. Rev.*

## GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION,  
1866.REPORT ON THE VISITATION OF EXAMINATIONS AT THE  
ROYAL COLLEGE OF PHYSICIANS OF LONDON.

By Dr. JOHN STORRAR and CÆSAR HENRY HAWKINS, Esq.

HAVING visited the examinations held in the course of the present month at the Royal College of Physicians, where we were courteously received, we beg to submit the following Report to the Branch Council for England:—

1. The College has altogether ceased to hold any preliminary examination of candidates for the licence, requiring proof of its having been undergone elsewhere.

2. Twelve candidates appeared for the primary examination for the licence, of whom nine were approved, and three rejected. They were required to write answers, within three hours, to six questions on anatomy and physiology; and, during a similar period, to five questions on chemistry, materia medica, and practical pharmacy; and were submitted to a *vivâ voce* examination of one hour's duration, equally divided between these two classes of subjects.

3. Six candidates, hitherto unqualified for practice, were examined for the pass examination for the licence, all of whom were approved. They were required to write answers, within three hours, to six questions on the principles and practice of medicine; and, during a similar time, to four questions on the principles and practice of surgery; and four questions on midwifery and the diseases of women and children; they were examined clinically at a hospital on medical and surgical cases at different times; and they were examined *vivâ voce*, during one hour and a half, equally divided between medicine, surgery, and midwifery.

Both of these examinations are conducted by special examiners on each subject, and in our opinion they afford a very fair and satisfactory test of the candidates' knowledge and fitness to practise.

4. There were examined at the same pass-examination for the College licence nine other candidates, who had been registered under some qualification before 1861, of whom two were rejected and seven succeeded. These candidates were exempted from every part of the primary examination, from all written examination, and from both clinical examinations, and were subjected solely to a *vivâ voce* examination for an hour and a half divided equally between the three subjects of medicine, surgery, and midwifery.

As, however, this class of candidates is obviously limited in number, and must hereafter have been at least five years registered, this practical examination may, in our opinion, be considered sufficient for its purpose.

5. Six candidates for the membership of the College were examined by the President and Censors, all of whom were approved. As, however, all these gentlemen were already legally qualified to practise, by holding university degrees, or by long standing as practitioners, we did not consider it consistent with our duty to attend their examination.

In the case of the very few candidates likely to claim the membership of the College as a first qualification for practising medicine, the greater age and more extended education required of them, and the more stringent examination in medicine to which they are subjected, as compared with that for the licence, render it no doubt amply sufficient.

REPORT ON THE VISITATIONS OF EXAMINATIONS AT  
THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.By Dr. WILLIAM SHARPEY, GEORGE COOPER, Esq.,  
AND E. A. PARKES, Esq.

The professional examinations at the College of Surgeons of England is divided into two parts:—

The first, primary, or anatomical and physiological examination.

The second, pass, or surgical and pathological examination. In addition, there is an examination for a licence in Midwifery.

During the present month we have attended the primary and the pass examinations. We were received with great courtesy, and every facility was given us, in order that we might learn the whole system of examination, and thoroughly scrutinize the manner in which it is carried out.

FIRST, OR ANATOMICAL AND PHYSIOLOGICAL  
EXAMINATION.

This examination is conducted in writing and orally.

On the 4th November we attended the written examination; there were seventeen candidates, seated at different tables, in the presence of the President, Mr. Wormald, and other officials. Every care was taken to prevent communication between the candidates. Six questions (annexed) were put, and three hours were allowed to answer them. The questions were selected by the President from a larger list, of which each member of the Court of Examiners furnished two. It will be seen that they go over a considerable range of anatomy, and are doubtless well adapted to test the candidates' knowledge of that subject. The subject of physiology is not embraced so fully in these questions, but we presume this subject is purposely made subsidiary to the anatomical part of the examination.

Each candidate was designated throughout the examination by a number assigned to him by the Secretary, and the papers of written answers, with the numbers but not the names attached, were sent round to the Examiners. Each paper was submitted to two Examiners, who then, irrespective of each other, reported the paper as good (G), moderate (M), or bad (B).

We were offered the perusal of the papers, but contented ourselves with three specimens, marked G, M, and B. Our own judgment upon these was in accordance with that of the Examiners. On 7th of November we attended the oral examination of the same candidates. On four tables were placed dissected portions of the fresh subject, and there were also dried and moist anatomical specimens, with an ample supply of bones and ligaments. Each candidate passed ten minutes at each of the two tables, and was therefore twenty minutes under examination. He was shown the dissected portion of a subject, and was asked to name the parts shown to him, or to point out parts named to him, and questions based on his answers were rapidly put. He was then examined on prepared specimens, such as the brain, heart, liver, bladder.

The candidate, after examination at one table, carried the record of it to the next, so that there was no risk of his being unintentionally asked the same questions. We consider this part of the examination extremely well conducted, and calculated to well and fairly test practical anatomical knowledge. The method of deciding whether a candidate has passed is as follows:—

As already stated, the written papers are marked good, moderate, or bad, by two Examiners. A similar judgment is passed at each table in the oral examination. The judgments are now copied into a book, and there will be, of course, four letters against each candidate's number—viz., the judgments of two Examiners on his written paper, and of the Examiners at the two tables in the oral examination.

If a candidate has four G's he passes, of course; he passes also if he has three G's and one M, provided the M is in the written examination. He may pass if he has two G's and two M's, provided both the M's are in the written examination. If he has one G and one B in the oral, and two G's in the written examination, he is further examined *vivâ voce*, and if the result is satisfactory, the B is changed to M, and he is allowed to pass; if not, he is rejected. If there are two G's, *vivâ voce*, and B and M in the written examination, the paper is read over to the whole court; if the B stands, he is rejected; if it is

changed to M, he is passed. In all other cases the candidate is rejected.

It will be seen from this plan that the College attaches more value to the twenty minutes' oral, than to the three hours' written examination. Out of the seventeen candidates examined on the occasion when we were present, eight were rejected. As we believe that a distinct expression of opinion is required of us, we have to report that the examination appeared to us a fair and sufficient test of that degree of anatomical knowledge which may be reasonably exacted of candidates for a qualification to be registered as practitioners in surgery.

#### SECOND, OR PASS, OR PATHOLOGICAL AND SURGICAL EXAMINATION.

This examination, like the former, is conducted in writing and orally. The written examination occupies four hours, the oral thirty minutes.

One of our number, Mr. Cooper, attended the written examination on the 11th November, when twenty-four candidates were present. It was conducted as at the former occasion. The questions, prepared as before described, are annexed. It will be observed that these are all good practical questions on subjects with which every candidate ought to be familiar. The answers are submitted to two Examiners, who mark their independent opinions as in the primary examination. Three of these papers, marked G, M, and B, were handed to us for perusal, and we agree with the judgments passed upon them. On the 14th two of our number (Drs. Sharpey and Parkes), and on the 15th and 16th Mr. Cooper, attended the oral examination. A number of tables were prepared, with preparations placed on them, and at each table at least two Examiners sat. One made notes of the questions which another asked, and the candidate carried this paper from table to table for the information of the subsequent Examiners. In case a candidate belonged to a school with which an Examiner is connected, he was not examined by that Examiner; and in this, and in all other arrangements, great care was evidently taken to ensure perfect fairness.

The candidates were practically tested, as far as it could be done, by the preparations on the table; but there was no practical testing of manual skill and readiness in such operations as passing catheters, putting on bandages, applying splints, &c., nor were the candidates required to show that they could perform operations on the dead subject. The decision respecting the candidates is made according to the letters placed against his number in the book, on the same plan as in the primary examination. The method adopted in both cases is, as far as we were able to judge, sufficient to afford a fair criterion of the performance of the candidates.

It is for the Medical Council to judge what branches of professional and scientific knowledge it is expedient to include in an examination for a qualification in surgery. Our present duty, we believe, will be discharged by reporting on the examinations actually gone through. We have already expressed an opinion on the primary examination. Of the second, which is confined to surgery, strictly so-called, it appears, if we may be permitted to judge, very well conducted as far as it extends; but, as already hinted, it seems desirable and we feel assured it is quite practicable, to subject the candidate to practical exercises in bandaging and other such appliances, and in operations on the dead subject, as far as the supply of subjects will permit.

To the Branch Council.

In the desirability of the last paragraph, I fully concur; but I must express my doubts as to its practicability. C.

REPORT ON THE VISITATION OF EXAMINATIONS AT APOTHECARIES' HALL, LONDON.

By Dr. EDMUND A. PARKES AND Dr. R. QUAIN.

Before granting the licence to practise, the Society of

Apothecaries of London consider it necessary to examine candidates on the following professional subjects:—

Anatomy and Physiology.

General and Practical Chemistry.

Botany and Materia Medica.

Practice of Medicine and Pathology.

Midwifery, including the Diseases of Women and Children.

Forensic Medicine and Toxicology.

Under the existing regulations, which are gradually being enforced in all cases, the examination on the three first-named subjects—viz., anatomy, chemistry, materia medica and botany, is passed after the second winter session—i.e., after the completion of two winter and one summer sessions. This is called

#### THE FIRST EXAMINATION.

Proficiency in anatomy and chemistry is tested by a written and by an oral examination; the written examination usually occupies an hour and a half for the two subjects. In order to give the Branch Council an idea of the scope of this written examination we append the questions given in anatomy and physiology and in chemistry on September 28th, October 26th, and November 30, 1865. It will be observed that four questions are put in anatomy and physiology, and four in chemistry. The questions are prepared by two or three examiners in regular rotation, are read out at a full Court of Examiners, and are then sealed up until the day of examination. It may or may not happen that the Examiners who prepare the questions have to decide on the answers.

The questions in anatomy are especially directed to what may be termed medical anatomy, and are intended so far to differ from the class of questions given at the College of Surgeons. In physiology, also, questions likely to bear on practice, or at any rate dealing with practical matters, are chosen. In chemistry the questions appear to be purely chemical.

Considering the period when this first examination is undergone, these questions appear to us to be well suited for their purpose. If well answered they would show, we think, a fair knowledge of these subjects. Probably as the system is matured the number of questions will be increased, and more time will be given for the replies.

The answers to these questions are at once read over by two Examiners, who mark on the paper the words Bene, Satis, or Male, and communicate their decision to the Examiners, who are about to examine the candidate *vivâ voce*.

We have been permitted to read some answers, and concur with the judgment of the Examiners thereupon.

After undergoing this written examination, the candidate on the same evening is examined orally in materia medica and botany, and possibly also in anatomy and physiology.

We attended the examination on the 9th and the 30th November. We found two and sometimes three Examiners seated at different tables, with anatomical preparations and specimens of drugs, chemical tests, botanical specimens (at certain times of the year), and microscopic preparations of medical subjects.

Each candidate is under examination for a variable time from half an hour to an hour and a half. He is especially tested on materia medica, pharmacy, and botany, on which there is no written examination. He reads and explains the Pharmacopœia, reads a written prescription, names drugs, describes their properties and uses, and may be called upon to use some simple chemical tests. If his answers are not satisfactory, other Examiners are summoned to the table, and the examination is prolonged. If he is rejected, the cause of the rejection is at once entered in a book.

Every candidate, whatever may have been his written examination, goes through this oral examination, and is virtually passed or rejected upon that.

At the same time the character of the written examination is taken into account.

With regard to the sufficiency of the examination on *materia medica*, if the object is merely to see if the candidate is familiar with the physical characters and properties of drugs, and knows the pharmacopoeial preparations, we think it sufficient. But we infer that the Examiners do not intend it to be an examination on therapeutics, which is, we presume, more properly deferred till the second examination, and is included in the examination on medicine.

#### SECOND EXAMINATION.

The subjects of this examination are practice of medicine, midwifery, and forensic medicine. The examination takes place at the end of the period of study, the five years' pupillage being completed.

There is a written examination on medicine and toxicology, and an oral examination on all the subjects. The mode of examination is precisely the same as in the former case, the written examination lasting one hour, and the oral rather longer than the first examination—viz., from one hour to one hour and a half. The questions are framed in the same way; the answers are read through, marked *Bene*, *Satis*, or *Male*, and the oral examination is carried on in a similar method.

We append the questions put on the 26th October, the 28th September, and 30th November. We have also read the answers given on the last named occasion.

It will be observed that four written questions are given in medicine, and the same in toxicology. This appears to us to be hardly in proportion to the importance of the subjects. Probably, as the Society of Apothecaries follow their invariable rule of gradually improving their examinations, they will increase the number of questions in medicine, and prolong the time of answering them.

The questions appear to us to be good; they are sensible practical questions, well adapted for testing the candidates, and neither above or below the standard which candidates for the licence ought to pass.

In midwifery there are no written questions, but we do not know the reason for this exception. We observe, however, that a certificate of attendance on no less than twenty labours is required, and therefore the Society may place reliance on the evidence of this previous experience.

There is no kind of practical examination in medicine, but we entertain little doubt that the Society will ultimately institute some test of this kind.

On the whole, considering the importance of this examination, we are inclined to think it should exceed in duration and severity the first examination, in a higher degree than is the case at present.

But in saying this we think it right to add that we are much impressed with the great care and attention given to every part of the examination, and with the evident desire to thoroughly test the candidates. We think, indeed, that the examination is really a good one. If we have ventured to indicate that a longer examination in medicine and therapeutics and in midwifery, and a practical examination of patients are desirable, we are certain that we are only anticipating the desire of the Society itself, for we cannot forget that ever since 1815, the Society of Apothecaries of London has steadily and judiciously brought into play a scheme of gradually increasing severity of examination, which has had the best effect on medical education.

We have stated the general course of the examination, but the present rules are subject to some exceptions. The present period is in fact one of transition. Gentlemen who have been long in practice, or who can bring forward evidence which satisfies the Court of Examiners of the reasonableness of the request, are sometimes excused the written examinations. Such cases are transitory, and the decision regarding them is best left entirely to the Society. We are assured, and we entirely credit the assurance, that the Court make it an invariable rule never to let a man pass who does not appear likely to make a safe and useful practitioner.

Another class of exceptions refers to gentlemen who

have passed the examination at the College of Surgeons, the College of Physicians, or other licensing bodies. They are also excused the written examination. We are not quite so well satisfied of the uniform propriety of this practice. No doubt it might seem unnecessary to examine in anatomy a candidate who has passed the College of Surgeons, but we see no reason why such a candidate should be excused the written examination in medicine, chemistry, and toxicology, on none of which subjects is he examined at the College of Surgeons. In the case of the College of Physicians it is different, as there he is examined in the very subjects which the Society of Apothecaries have to deal with.

In conclusion, we must express our thanks to the Chairman and to the Court of Examiners and the Secretary, for the courtesy with which we were received, and for the great pains taken to make us acquainted with the whole system of examination.

#### REPORT ON THE VISITATION OF EXAMINATIONS AT THE UNIVERSITY OF OXFORD.

By DR. PAGET, M.D., AND DR. RICHARD QUAIN, M.D.

By appointment of the Branch Medical Council for England we attended the examinations for the degree of Bachelor of Medicine at Oxford during the present month. These examinations are held once a year, and always during the Michaelmas term. There are two examinations which must be passed by every candidate for the degree of B.M. The first in anatomy and physiology, and other elementary subjects. The second in pathology and practical subjects. The first examination is held in the week preceding the second, but on this occasion (with great consideration for our convenience, but not we fear without inconvenience to the Examiners), both examinations were conducted simultaneously.

#### THE FIRST EXAMINATION.

The following are the regulations under which candidates are eligible for admission to this examination:—

"No candidate can offer himself for the first medical examination until two years have elapsed from his passing his final classical examination for the degree of B.A.

"To obtain the degree of B.M. he must have passed (besides the two medical examinations) all the examinations required for the degree of B.A., but he need not take the degree of B.A.

"These rules are the only rules affecting candidates in the present year, but in consequence of changes in the Statute of Examination in Arts, some of these rules will for the future be inapplicable, and some change in the Medical Statute is requisite, which has not yet been made.

"The general principle is that the students in medicine shall have had as good an arts education, *prior to* scientific and medical study, as ordinary art students.

"Various minor changes consistent with this principle are in contemplation for making as simple and complete as possible the arrangements for testing the scientific attainments of the medical candidates and other allied objects."

The examination extends over four days, and includes the following subjects:—physics, chemistry, anatomy and physiology, and botany.

The first three days are occupied by the three examinations in writing, and two practical examinations, one in anatomy, and the other in chemistry. The fourth day is devoted to a general *visà voce* examination on all the subjects, in which various specimens, including microscopic objects, are submitted to each candidate. Annexed will be found a scheme showing the days and hours appropriated to this examination, together with the questions to which written answers were required.

The examinations were conducted by four examiners—viz.: Dr. Acland, F.R.S., Regius Professor of Medicine.

Dr. Rolleston, F.R.S., Linacre Professor of Physiology.

Mr. Henry Smith, M.A., F.R.S., Savilian Professor of Geometry.

Mr. Vernon Harcourt, M.A., Lee's Reader in Chemistry.

The Regius Professor of Medicine is the only permanent examiner, and presides *ex officio*. The other examiners, who must be members of Convocation, are appointed annually by the Vice-Chancellor.

There were five candidates under examination, and we observed that each candidate was examined at the *visâ voce* examination by each examiner in turn, all the examiners being seated at the same table. We also observed that one examiner abstained from examining a candidate who happened to belong to his own College, in accordance with the practice at Oxford. The examination was public, and we observed that some of the undergraduates were present.

The printed papers annexed will show very clearly the extent and the practical character of the examinations.

With the exception of botany, the examination on which is confined to two questions contained in the papers on anatomy and physiology, we think that the questions are all that could possibly be desired. They are varied in character, eminently practical, and well calculated to test the knowledge of the candidates.

The efficiency of any system of examination must, however, be tested rather by the answers of the candidates than by the questions proposed. We have to acknowledge that information on this latter point was most freely given us. The written answers of all the candidates were placed in our hands. We examined those of one candidate, which were considered satisfactory, and of another candidate, which were considered not satisfactory. The former passed, the latter was rejected.

The opinion we formed was entirely in accordance with the decision of the examiners. We did not remain in Oxford until the final decision on this examination. We have been since informed that of the five candidates two were rejected.

#### THE SECOND EXAMINATION.

Candidates are admitted to this examination after an interval of two years from the date of passing the first examination.

The examination extends over three days, and includes the following subjects:—

Pathology, therapeutics, diseases of women and children, principles of surgery, forensic medicine, and hygiene.

The two first days are devoted to written examinations, the third day to a practical examination of cases and of specimens in the Radcliffe Infirmary and to a public *visâ voce* examination on the cases and written papers.

Annexed will be found a scheme showing the days and hours assigned to this examination, together with copies of the examination papers, including extracts from a Greek and a Latin author (Aretæus and Celsus), which the candidate was required to translate and criticise by the light of modern pathology and practice.

There were three examiners present—viz.:—Dr. Acland, F.R.S., Regius Professor of Medicine; Dr. Thomas King Chambers, Consulting Physician to St. Mary's Hospital, London; Dr. John William Ogle, Assistant-Physician to St. George's Hospital, London.

The Regius Professor is a permanent examiner, and presides *ex officio*. The other examiners, who must be Doctors of Medicine and Members of Convocation, are appointed annually by the Vice-Chancellor.

There were three candidates under examination, and the examination was conducted as the first examination already described. The printed papers annexed will enable the Branch Councils to form an opinion on the extent and character of the tests to which the candidates were submitted. They seem to us all that could be desired, with this exception, that the examination on the subject of *materia medica* is confined to two questions on pharmacopœial preparations, to be found in the therapeutical paper.

We were present throughout the *visâ voce* examination, which occupied about an hour for each candidate, and we were also afforded an opportunity of reading all the written answers of the candidates. All the candidates were ap-

proved. The decision of the examiners was in accordance with the impression we had formed on the character of the answers.

On inquiry with reference to the examinations generally, we were informed that each examiner prepares his own questions, which are all forwarded to the Regius Professor of Medicine, who must be present at all the examinations.

In estimating the value of answers the examiners use numbers, or any other system at discretion. If a candidate fail to pass in any one subject he is rejected.

In concluding this report of our visitation of the medical examination of the University of Oxford, we have to express our warmest thanks to the authorities of the University for the desire which they exhibited to facilitate in every way the object of our visit, and to afford us the fullest information on every point into which we thought it necessary to inquire.

#### REPORT ON THE VISITATION OF EXAMINATIONS AT THE UNIVERSITY OF CAMBRIDGE.

By Dr. HENRY W. ACLAND AND Dr. DENNIS EMBLETON.

There were three candidates for the first M.B. examination, two for the second, one for the Master in Surgery. Of the six candidates one retired without answering questions, one was rejected. The other four passed.

The Examiners were:—

#### FOR FIRST M.B. EXAMINATION.

Dr. Bond, Dr. Drosier for Dr. Clark, Mr. Liveing, *ex officio*.

Dr. Hare, Dr. Lathan, Dr. Humphry, appointed.

#### FOR SECOND M.B. EXAMINATION.

Dr. Bond, Dr. Fisher, Dr. Drosier for Dr. Clark, *ex officio*.

Dr. Paget, appointed.

#### FOR M.C. EXAMINATION.

Dr. Drosier for Dr. Clark, *ex officio*.

Dr. Humphry, Mr. Holmes, appointed.

The annexed schedule shows the dates of, and the time occupied by, the examinations. (See No. 1).

The Examiners meet before the time of examination, to settle the questions for the printed papers; these are then printed at the University Press, and sent to one of the Examiners under the University Seal.

The examinations are carried on in the rooms of the Anatomical Museum and in Addenbrooke's Hospital:—

1. By printed papers of questions (a copy of which, for Michaelmas, 1865, is hereto appended, No. 2); during the answering of which Examiners are present.

2. *Visâ voce* on all the subjects of examination.

3. Practically,

a. On microscopic specimens, } (1st M.B.)  
On museum preparations }

b. On fresh dissections in the Dissecting-room. (1st M.B. and M.C.)

c. In the Laboratory: analysis, determination, &c. (1st M.B.)

d. In the Hospital, on medical (2nd M.B.), and on surgical cases (M.C.)

The examinations are open to members of the Senate of the University—i.e., to Doctors and Masters of Arts, &c. See Dr. Paget's letter annexed, and marked No. 3.

We wish to record that every courtesy was shown to the Members of the Council who attended on its behalf on the part of the University, and on that of the Medical Examiners, and every facility was freely offered for the discharge of their duty.

Notes were taken of the *visâ voce* and of the practical examinations. The written answers to the printed questions were offered and sent to the visitors, and have been perused by them. The hospital patients, whether medical or surgical, had on the morning of the practical examination just been received, and had not before been examined by any students.

In conclusion, we confidently certify that the examina-

tions and course of study are "such as to secure the possession." by persons obtaining the above-mentioned medical and surgical qualifications of the University of Cambridge, "of the requisite knowledge and skill for the efficient practice of their profession."

REPORT ON THE VISITATION OF EXAMINATIONS AT THE UNIVERSITY OF LONDON.

By Dr. GEORGE BURROWS, M.D., and Dr. JAMES ALDERSON, M.D.

We have to report that we singly or together visited several of the examinations for the degree of Bachelor of Medicine of the London University, conducted at Burlington House. That we have been most courteously received, and that every opportunity has been afforded us to witness the examination of the candidates and to judge of their proficiency.

The visitation consisted in attendance at Burlington House at the time of the examinations in general pathology and medicine, and in medical jurisprudence. Also in accompanying the candidates into the wards of King's College Hospital and observing the methods of testing their capabilities in clinical medicine.

The visitation also included the perusal of the papers of the least proficient of those candidates who obtained their diploma, consisting of their answers in general pathology and medicine, as well as the written histories of the cases taken in the wards of King's College Hospital by the two least proficient candidates.

Those of the least proficient candidates gave evidence of sufficient medical attainment for the degree of the University, but were not so satisfactory as regards general acquirement.

The examinations were well conducted, and a fair opportunity was afforded to the candidates, especially in the later papers, to display the extent of their acquirements.

The practical examination in medical jurisprudence struck us as especially worthy of imitation by other licensing bodies.

Attended the practical medical jurisprudence examination, Dr. Odling.

Six candidates were examined.

Six small tables with sets of test-tubes, and a desk of tests, spirit lamp, &c., complete.

Six specimens of commoner class of poisons presented to each in small powder, three coloured, three white, to be analyzed then and there; examine what they are. The mode of examination; the tests; the results to be put down on paper, for which pen and ink, &c., are provided.

One hour and a half is given for such analysis.

This seems a very efficient mode of examination, and to be followed at the College of Physicians. Facilities are now given at all the chemical classes in the schools of the metropolis for due preparation for such an examination.

The minutes of the last meeting were read and confirmed.

REPORT ON THE REGISTRATION OF MEDICAL STUDENTS.

1. The Committee, having taken into consideration the working of the system of registration of students of last session, find that in each division of the kingdom there have been a certain number of students unregistered, in consequence of the difficulty of making the new regulations sufficiently understood by the students and their friends, and by the authorities of the several Universities, Schools, and Hospitals; but they believe that this difficulty is likely to be materially lessened in future years, and they recommend that the Council should leave the several Branch Councils to make such exceptions in reference to the year 1865 as may seem to them advisable, enforcing the regulations strictly for the future.

2. The Committee have also considered "the cases of students admitted to registration who have not passed the Examination in Arts, or only a portion of such examination," and they find that in certain schools several stu-

dents have been allowed to commence their recognized medical education before having passed a preliminary Examination in Arts; but they do not find that any student has actually been registered before having passed the preliminary examination.

The Committee strongly disapprove of the above irregularity on the part of schools, and recommend that in future the whole of the preliminary examination should be required to be passed at one time, and that before either registration be allowed or medical education be commenced; and this recommendation, from the assurances they have received, they believe will now be literally complied with.

With respect to the students concerned, the Committee see no other course open to them than that of advising the Council that, under the circumstances named, they should be left to the favourable consideration of the Branch Councils, for they consider that it would be hard that, in the first year of a new system of registration, students should suffer through the irregularities above referred to.

3. The Committee have also paid attention to the "letter from Dr. Steele, Registrar of the Branch Council for Ireland, with an application from a student to be registered," and recommend that as the registration of medical students has been placed under the charge of the branch registrars, the decision in this case be left to the Branch Council for Ireland.

4. The Committee have carefully gone over the whole of the regulations respecting the registration of students, as laid down by the Council during the last Session, have remodelled them in accordance with existing circumstances, and beg leave to submit them in the following form for the approval of the Council, believing as they do that, having been made more simple and clear, the new regulations will be found well adapted to secure for the future a correct register of medical students.

REGISTRATION OF MEDICAL STUDENTS, 1866.

The following regulations have been adopted by the General Medical Council, in reference to the registration of medical students:—

1. Every medical student shall be registered in the manner prescribed by the General Medical Council.
2. No medical student shall be registered until he has passed a preliminary examination, as required by the General Medical Council.
3. The commencement of the course of professional study recognized by any of the qualifying bodies, shall not be reckoned as dating earlier than fifteen days before the date of registration.
4. The registration of medical students shall be placed under the charge of the Branch Registrars.
5. Each of the Branch Registrars shall keep a register of medical students according to the subjoined form:—

FORM FOR THE REGISTRATION OF MEDICAL STUDENTS.

| Date of Registration. | Name. | Preliminary Examination and Date. | Place of Medical Study. |
|-----------------------|-------|-----------------------------------|-------------------------|
|                       |       |                                   |                         |

6. Every person desirous of being registered as a medical student, shall apply to the Branch Registrar of the division of the United Kingdom in which he is residing, according to the annexed form, which may be had on application to the several qualifying bodies, medical schools, and hospitals; and shall produce or forward to the Branch Registrar, a certificate of his having passed a preliminary examination, as required by the General Medical Council, and a statement of his place of medical study.

FORM OF APPLICATION FOR REGISTRATION AS A MEDICAL STUDENT.

I hereby apply to be registered as a student in medicine, in conformity with the Regulations of the General Council

of Medical Education and Registration of the United Kingdom, for which purpose I submit the following particulars.

| NAME OF APPLICANT<br>(To be written in words at length.) |                 | Preliminary Examination. | Date of Preliminary Examination. | Place of Medical Study. |
|----------------------------------------------------------|-----------------|--------------------------|----------------------------------|-------------------------|
| Surname                                                  | Christian Name. |                          |                                  |                         |
|                                                          |                 |                          |                                  |                         |

Applicant's Signature \_\_\_\_\_

Address \_\_\_\_\_

Date of Application \_\_\_\_\_

To the REGISTRAR of the  
BRANCH COUNCIL for \_\_\_\_\_

N.B.—The above form of Application, duly and legibly filled up, must be forwarded to the Registrar, post free, and be accompanied by a Certificate of the Applicant's having passed a Preliminary Examination, as required by the General Medical Council; and a statement of his place of medical study.

Students who have commenced their professional studies more than fifteen days before the 2nd October, 1865, are not required to be registered by any Branch Registrar.

7. The Branch Registrar shall enter the applicant's name, and other particulars, in the Students' Register, and shall give him a certificate of such registration.

8. Each of the Branch Registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students.

9. The several Branch Councils shall have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear satisfactory.

10. A copy of the register of medical students, prepared by each of the Branch Registrars, shall be transmitted, on or before the 31st December in each year, to the Registrar of the General Council, who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered during the year, and supply copies of such authorized list to each of the bodies enumerated in Schedule (A) to the Medical Acts, and through the Branch Registrars to the several medical schools and hospitals.

11. The several qualifying bodies are recommended not to admit, after October, 1870, to the final examination for a qualification under the Medical Acts, any candidate (not exempted from registration) whose name had not been entered in the medical students' register at least four years previously.

In the case of candidates from other than schools of the United Kingdom, the Branch Councils shall have power to admit exceptions to this recommendation.

LETTER FROM THE METRIC COMMITTEE OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

To the General Council of Medical Education and Registration.

"10, Farrar's Building, Temple, May, 1866.

"GENTLEMEN,—We are desired by the Metric Committee of the British Association for the Advancement of Science to seek your aid in promoting the practical adoption of the Metric Weights and Measures Act, passed in 1864, being the 27 and 28 Vict., c. 117: 'An Act to render permissive the use of Metric Weights and Measures in the United Kingdom.' Although this law is of a permissive character only, yet it allows full scope for the extensive application of the new system, and we trust that every opportunity will be seized for resorting to it, with a view of putting an end to the manifold defects and inconveniences of the present practice.

"We understand, with pleasure, that such an opportunity now occurs for introducing the metric decimal system into medicine and pharmacy, since the British Pharmacopœia, published in January, 1864, is about to appear in a second edition. The objection formerly urged to the introduction of the metric system side by side with the imperial, in all

the formulæ for the preparation of drugs and chemicals, that the metric weights and measures were not yet sanctioned by the legislature, is now removed by the passing of the Act; and we hope, therefore, that your Council will give its sanction to the proposed useful addition.

"In submitting to you the desire of the Metric Committee of the British Association, that the knowledge of the metric system may be promoted in medicine and pharmacy, we would only add that, for international purposes, and especially for the use of foreign practitioners, and of British chemists in foreign countries, the ready comparison of the imperial with the metric weights and measures will be of great practical value; and, moreover, will tend to give effect to a reform expected to be highly useful to this country, and of extensive influence in social and international intercourse.—We have the honour to be, Gentlemen, your obedient servants,

"JOHN BARING, F.R.S., L.L.D.,  
Chairman of the Committee.

"JAMES YATES, M.A., F.R.S.,  
Member of the Committee."

Dr. ALEXANDER WOOD moved that this letter should be referred to the Pharmacopœian Committee for their consideration.

Dr. APJOHN and Dr. SHARPEY objected to this course, the latter gentleman proposing in lieu thereof the following resolution, which, on the withdrawal by Dr. Wood of his motion, was agreed to—"That the General Medical Council were not prepared to adopt, in its full extent, the suggestion of the Metric Committee of the British Association, but the Council will direct that a complete comparative table of metric and imperial weights and measures, with instruction for their mutual conversion, shall be inserted in the forthcoming edition of the British Pharmacopœia."

REPORT OF THE COMMITTEE ON RETURNS OF EXAMINATIONS AND THEIR RESULTS FROM THE LICENSING BODIES, AND ON THE REGISTER OF MEDICAL STUDENTS FOR THE LAST YEAR.

The Committee beg leave to lay before the Council:

1. A table, accurately compiled from the returns of examinations and their results, from the licensing bodies, according to Recommendation 6, section V., of the Recommendations of the General Medical Council of 1865; and have to remark that these returns have this year assumed a more complete and regular form than heretofore.

FORM OF RETURN.

According to the Recommendation 7, Sect. IV., of the Report of the Select Committee on Education, May 6, 1864 (previously Recommendation No. 23), of the General Medical Council, 1862.

| LICENSING BODIES.  | PASSED.              |                     | REJECTED.            |                     |
|--------------------|----------------------|---------------------|----------------------|---------------------|
|                    | 1st Examin. Number.  | 2nd Examin. Number. | 1st Examin. Number.  | 2nd Examin. Number. |
| R. C. P., Lond.    | 75                   | 75                  | 10                   | 13                  |
| R. C. S., Engl.    | 372                  | 365                 | 192                  | 53                  |
| Soc. Apoth., L.    | 281                  | 264                 | 23                   | 22                  |

| Apoth. Hall, Ire.  | 12                   | 30                  | 4                    | 4                   |
| Univ. of Dublin    | 12                   | 30                  | 4                    | 4                   |
|                    | 1343                 | 1578                | 313                  | 233                 |

\* By the regulation, University candidates are allowed, under certain conditions, to postpone their examination in physiology until the first M.B. examination of a subsequent year.

+ In this return, those gentlemen having the letter D prefixed to their names in both columns, were candidates for the double qualification in medicine and surgery of the Royal Colleges of Physicians and Surgeons of Edinburgh.

\* Final examination for M.D. under old regulation.

2. The Committee find, on examination of the students' register for last year, that it contains a list of all students registered by the Branch Councils, in compliance with the Recommendations in section XI. of the Report on Education, of April 15, 1865, and that the entries extend from October 1st, 1865 (when they were ordered by the Council to be commenced), to February 19th, 1866.

The numbers so registered are as follows—viz.:

|                      |     |
|----------------------|-----|
| In England . . . . . | 313 |
| Scotland . . . . .   | 128 |
| Ireland . . . . .    | 212 |

Total . . . . . 653

Of these they find that eight students registered in England, and sixty in Scotland, belong to the year 1866, whilst the register for Ireland is strictly confined to 1865. They recommend that the names of these sixty-eight students, in order to keep their yearly registers distinct, shall be carried on to the register of 1866; this would leave for 1865 the following number of students registered:

|                      |     |
|----------------------|-----|
| In England . . . . . | 305 |
| Scotland . . . . .   | 68  |
| Ireland . . . . .    | 212 |

Total . . . . . 585

This total, however, is very far from representing the actual number of students who have commenced their medical education in the United Kingdom during the year 1865, for the Committee have learnt that, for instance, at St. Mary's Hospital, London, forty students have been entered who have not been registered by the Branch Registrar for England, as required by the General Medical Council.

It is probable that other students in the three divisions of the kingdom are in the same case, but to what amount the Committee have no means of ascertaining.

This statement will be sufficient to enable the Council to form an opinion as to the present very imperfect state of the students' register; and though it is much to be regretted that this great imperfection exists, yet the Committee trust that when the revised and simplified recommendations of the present session become thoroughly known and understood, this imperfection, by the loyal and willing co-operation of the bodies in Schedule (A), will next year disappear.

D. EMBLETON, Chairman.

#### RECOMMENDATIONS OF THE GENERAL MEDICAL COUNCIL, ON THE SUBJECTS OF PRELIMINARY EXAMINATION, OF REGISTRATION OF MEDICAL STUDENTS, AND OF PROFESSIONAL EDUCATION AND EXAMINATION, 1866.

##### I.—PRELIMINARY EXAMINATION.

1. That testimonials of proficiency granted by the National Educational Bodies according to the subjoined list, may be accepted, the Council reserving the right to add to, or take from, the list.

1. A Degree in Arts of any University of the United Kingdom or of the Colonies, or of such other Universities as may be specially recognized from time to time by the Medical Council.
2. Oxford Responsions or Moderations.
3. Cambridge Previous Examinations.
4. Matriculation Examination of the University of London.
5. Oxford Middle Class Examinations (Senior).
6. Cambridge Middle Class Examinations (Senior).
7. Durham Middle Class Examinations (Senior).
8. Durham Examinations for Students in Arts in their Second and First Years.
9. Durham Registration Examination for Medical Students.
10. Dublin University Entrance Examination.
11. Queen's University, Ireland, two years' Arts Course for the Diploma of Licentiate in Arts.
12. Preliminary Examinations at the end of A.B. Course.
13. Middle Class Examinations.
14. Matriculation Examinations.

15. First Class Certificate of the College of Preceptors.
16. "Testamur" granted by Codrington College, Barbadoes.

17. Degree of Associate of Arts granted by the Tasmanian Council of Education, with a certificate that the Student has been examined in Latin and Mathematics.

2. That students who cannot produce any of the testimonials referred to in the first recommendation be required to pass an Examination in Arts, established by any of the bodies named in Schedule (A) to the Medical Act, and approved by the General Medical Council.

3. That the examination in general education be eventually left entirely to the examining boards of the national educational bodies recognized by the Medical Council.

4. That no certificate of proficiency in general education, which does not affirm the proficiency of the candidate in Latin, be deemed a sufficient proof of preliminary education previous to the commencement of professional studies.

5. That the various educational and licensing bodies be requested to transmit to the Registrar of the General Council, returns, embodying any alterations which they may from time to time introduce into their courses of general study and examinations, which qualify for the registration of medical students; and that a copy of such returns be sent by the Registrar, as soon as convenient, to each Member of the General Council.

N.B. The following recommendations, printed in red, were passed by the General Medical Council, May 25th, 1866, but are not intended to come into operation till October 1st, 1868.

1. That the following subjects constitute a minimum to be required of candidates for preliminary examination, viz.:

##### Compulsory Subjects—

1. English Language, including Grammar and Composition.
2. Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations.
3. Geometry: First Two Books of Euclid.
4. Latin, including Translation and Grammar.

and 5. One of the following

##### Optional Subjects—

1. Greek. After the year 1869 Greek shall be one of the compulsory subjects.
2. French.
3. German.
4. Natural Philosophy, including Mechanics, Hydrostatics, and Pneumatics.

2. That certificates of proficiency, to be received from all bodies legally authorized to examine in general education in Great Britain and Ireland, and from the several licensing bodies enumerated in Schedule (A) to the Medical Act in Great Britain and Ireland, shall bear evidence that the candidates have been examined and approved in at least the above subjects.

3. That in the case of certificates received from similar educational and licensing bodies in other parts of the empire and foreign countries, satisfactory evidence shall be given to the Medical Council (or Branch Councils) that such certificates are equivalent to those recognized in the United Kingdom.

4. That it shall be delegated to the Executive Committee to prepare annually and lay before the Council for recognition a list of examining bodies, whose examinations shall fulfil the conditions of the Medical Council as regards preliminary education.

5. That the regulations of the General Medical Council as to preliminary education, adopted during the present Session, shall not come into operation till October 1st, 1868, and that in the meantime the previous regulations shall remain in force.

##### II.—PROFESSIONAL EDUCATION.

1. That the course of professional study required for a licence shall comprehend attendance during not less than

four winter sessions, or three winter and two summer sessions, at a school recognized by any of the licensing bodies mentioned in Schedule (A) to the Medical Act.

2. That it be recommended to the several licensing bodies that the courses of instruction required by them be framed in such a manner as to secure a due share of attention, both to preparatory branches and to those more strictly connected with the practice of medicine and surgery; and that it be suggested accordingly to these bodies, that their regulations should be such as to prevent attendance upon lectures from interfering with hospital and clinical study.

3. That the Council will view with approbation any encouragement held out by the licensing bodies to students to prosecute the study of the natural sciences before they engage in studies of a strictly professional character.

### III.—AGE FOR LICENCE TO PRACTISE.

1. That the age of twenty-one be the earliest age at which a candidate for any professional licence shall be admitted to his final examination; that the age shall, in all instances, be duly certified; and that a return of any exceptions to this recommendation allowed by the licensing bodies, together with the reasons for such exceptions, be transmitted to the Branch Council of that part of the United Kingdom in which they have been granted.

2. That no licence be obtained at an earlier period than after the expiration of forty-eight months subsequent to the registration of the candidate as a medical student.

### IV. PROFESSIONAL EXAMINATION.

1. That those licensing bodies which have not already done so, be requested to furnish a statement of the dates of their examinations and of the modes in which such examinations are conducted, whether by written, oral, or practical examination, and of the length of time a candidate is under examination in each or all of these ways; and that the Registrar transmit these reports to the Members of the Council, in order that they may be taken into consideration at the next meeting of the several Branch Councils.

2. That the professional examination for any licence be divided into two parts; the first embracing the primary or fundamental branches directly connected with the practice of medicine and surgery; that the former be not undergone till after the close of the winter session of the second year of professional study; and the latter or final examination, not till after the close of the prescribed period of professional study.

3. That the examination in physics, botany, and natural history may be undergone at an earlier period than the first professional examination.

4. That the professional examinations be conducted both in writing and orally; and that they be practical in all branches in which they admit of being so.

5. That the professional examinations be held by the several licensing bodies, except in special cases, at stated periods, to be publicly notified.

6. That returns from the licensing bodies in Schedule (A) be made annually, on the 1st of January, to the General Medical Council, stating the number and names of the candidates who have passed their first as well as their second examinations, and the number of those who have been rejected at the first and second examinations respectively; and that the Registrar forward a sufficient number of forms, with a notice for their being returned in due time.

7. That it be recommended to all the examining boards that they should require from every candidate for examination before them, a statement, signed by himself, whether he has, or has not, been rejected within three months by any of the examining boards included in Schedule (A) to the Medical Act.

8. That it is not desirable that any University of the United Kingdom should confer any degree in medicine or surgery, whether that of Bachelor, Doctor, or Master, upon candidates who have not graduated in Arts, or

passed all the examinations required for the Bachelorship in Arts, or the examinations equivalent to those required for a degree in Arts.

### V.—SUPERVISION OF EXAMINATIONS.

1. That the visitations of the examinations, preliminary as well as professional, of the qualifying bodies, by the Branch Councils, or such of their members as they may depute, be continued during the ensuing year.

2. That the reports of the visitors shall apply to every part of the examinations of each body, and shall include a statement of the facts observed and of the opinions of the visitors as to the efficiency of the examinations; as also such remarks and suggestions on defects in them as circumstances may indicate.

3. That the reports of the visitors be submitted in the first instance to the Branch Councils; and that thereafter the Branch Councils shall direct them to be printed and circulated confidentially amongst the members of the General Council, so that they may be in a condition, at the meeting of the General Council in 1867, to consider them maturely.

### LETTER FROM THE PRESIDENT OF THE CHEMICAL SOCIETY.

*To the President of the General Council of Medical Education and Registration.*

"Burlington House, 19th March, 1866.

"SIR,—The President and Council of the Chemical Society venture to call the attention of the Medical Council to the system of Chemical Notation adopted in the British Pharmacopœia; and as they are informed that a new edition of that Pharmacopœia is in course of preparation, they entertain a hope that it may not be an inopportune moment to urge upon the Medical Council the desirableness of considering whether, in the forthcoming edition of the work, the use of chemical symbols could not be advantageously dispensed with altogether. In the few cases which may seem specially to call for the use of such formulæ, a percentage representation of the composition of the body would, it appears, supply all the necessary data.

"The grounds on which the President and Council of the Chemical Society have been induced to suggest this course are these:—

"The system of Notation at present adopted in the British Pharmacopœia is constructed in conformity with views which are rapidly disappearing from chemical teaching in this country.

"The Pharmacopœia is necessarily the text-book on which the examinations of students of medicine and pharmacy in pharmaceutical chemistry are based. It appears, therefore, extremely desirable that no works shall be put forth on official authority, such as that of the Medical Council, which shall be at variance with the views propounded by many of the most active experimental leaders and principal teachers of chemical science; or which shall oblige the teacher to adopt a double numerical system in his exposition of the facts of chemical science to his pupils—a course which is always a source of embarrassment both to professor and learner.

"It is obvious that the adoption of a plan such as the one now suggested does not necessitate any expression of opinion on the part of the Medical Council upon a subject which is still under discussion. At the same time, it will relieve the Council from the inconvenience of appearing pledged to the maintenance of doctrines which are no longer believed to be correct by many of the most competent to form an opinion on the subject.

"The President and Council of the Chemical Society trust that the importance of the subject will sufficiently explain their anxiety to bring this matter under the consideration of the Medical Council.

"WM. ALLEN MILLER, President of the Chemical Society.  
"To Dr. Burrows."

Moved by Dr. QUAIN, seconded by Dr. STORRAR, and agreed to:—"That the letter addressed by the President of the Chemical Society to the President of the Medical Council be entered on the minutes."

2. Moved by Dr. STORRAR, seconded by Dr. ALDERSON, and agreed to:—"That as soon as the proof of the new edition of the Pharmacopœia is ready, a copy of it be sent

to each member of the Council, with instructions that he will, within one month, return it to the Secretary of the Pharmacopœia Committee, with such observations as he shall see fit to make thereon, to be submitted to the Pharmacopœia Committee; and that the Pharmacopœia Committee shall, after due consideration of such observations, hand over the proof, when finally approved, to the Executive Committee for publication."

3. Moved by Dr. APJOHN, seconded by Dr. A. SMITH, and agreed to:—"That it be an instruction to the Pharmacopœia Committee to give for each therapeutic compound, of definite constitution, occurring in the forthcoming edition of the Pharmacopœia, two formulæ,—the first being that in ordinary use at present, the second being one constructed in accordance with the more recent views of what is called the 'unitary system.'"

4. Moved by Dr. ACLAND, and seconded by Dr. PAGET:—"That it be an instruction to the Pharmacopœia Committee to take steps to ascertain whether any or what limits have been imposed by the Medical Act, on the reports and investigations which the General Council might see fit to obtain or direct, into the properties of the medicines and compounds of which the Council is required to furnish a list; and specially whether the Council is limited by the Act to enquiries as to the composition of articles of the materia medica, and the modes of preparing and compounding them."

The motion was not carried, there being nine votes for, and nine against it.

Dr. ACLAND required that the names and numbers of those who voted and those who declined to vote, be taken down.

For 9.—Drs. Acland, Paget, Alexander Wood, Thomson, Leet, Apjohn, Parkes, Christison, and Stokes.

Against 9.—Mr. Cooper, Drs. Embleton, Storrar, Andrew Wood, A. Smith, Hargrave, Sir D. J. Corrigan Dr. Sharpey, and Dr. Quain.

Declined to vote.—The President, Dr. Alderson, Mr. Hawkins, and Dr. Fleming.

5. Moved by Dr. CHRISTISON, seconded by Dr. QUAIN, agreed to:—"That the report of the Pharmacopœia Committee (Minutes, General Council, for May 25, 1866, No. 90, p. 6) be adopted.

MONDAY, MAY 28TH.

The first business of to-day was a consideration of the report of the Committee in reference to the letter received from the Secretary of State for War.

The Committee suggested that the following communication be forwarded in reply:—

SIR,—I am directed by the General Medical Council to acknowledge the receipt of your letter of the 26th, in which you inform me that Lord de Grey requests the Medical Council will favour him with their opinion as to the particular initials which should be used to designate the several medical qualifications described in the table appended to the Medical Act, and for which abbreviations are therein laid down. For example, Licentiates of the King and Queen's College of Physicians in Ireland, in the table of abbreviations appended to the above-named Act, are thus described, "Lic. K. Q. Coll. Phys., Ireland." What initials should be used in this and similar cases?

With regard to the first question, the General Medical Council submits, that it is only necessary to follow the precedent already existing in regard to the title "Surgeon" in the Army List. The title or qualification "Surgeon" (for it is both) does not mark the particular College or University which has conferred the required qualification, but leaves that to be ascertained by the *Medical Register*, published under Act of Parliament.

In like manner, in regard to medical qualifications the initials "M.D." or "M.B." are inserted after Surgeons, names, indicating that they possess such qualifications without distinguishing the particular Universities from which those titles are obtained.

It appears to the General Medical Council that, following those precedents, it is only necessary in like manner to insert after the names of surgeons having medical qualifi-

of England, Ireland, or Scotland, or from any University giving a licence in medicine, the letters, "Ph.," signifying Physician, indicating that the qualification is that of Physicians, in like manner as in the initial letters, "M.D." and "M.B.," not distinguishing the particular College or University from which the title "Physician" is obtained.

These observations apply equally to the only other initial letters proposed in the case of Licentiates of Apothecaries' Companies of England and Ireland, viz.; that the initial letters "Ap." should be inserted in like manner, indicating the qualification without distinguishing the particular company from which the qualification has proceeded.

With regard to the second question—viz.:

"In the case also of a surgeon who possesses more than one medical qualification the Council is requested to specify which should be selected for insertion in the Army List. Suppose, for illustration, a Licentiate of the King and Queen's College of Physicians, Dublin, is also a doctor of medicine of the University of Edinburgh, or a member of the London College of Physicians, or a Licentiate of the Society of Apothecaries; which of these medical qualifications is to have precedence, and by whom is this to be decided?"

The General Medical Council does not apprehend any difficulty.

The case put of a surgeon having more than one medical qualification is, and will be, of frequent occurrence in the army. It is not uncommon for an army surgeon to have two medical qualifications, one of "M.B." or "M.D." of a University, and another "Ph." from a College of Physicians.

It is only necessary to signify that one medical qualification alone will be inserted, leaving it to the discretion of the surgeon himself as to which he would select, or whether he would select any. A surgeon who has two medical qualifications—for instance, one from a Royal College of Physicians, and another from a University, may desire to have "M.D.," the University qualification, after his name; while another similarly circumstanced, may desire to have "Ph." after his name, designating that he is a physician.

It is also of ordinary occurrence, and is a practice very much to be encouraged, that army surgeons take advantage of opportunities from leave of absence, or from being stationed where there are celebrated medical schools, to acquire a medical qualification higher than that they had on entering the army, and such surgeons the General Medical Council apprehends would, of course, have the liberty of substituting from time to time the higher qualification for the original qualification inserted.

In conclusion, I am to observe that the additional initials proposed to be inserted in the Army List would be only two—viz.:

|     |             |
|-----|-------------|
| Ph. | Physician.  |
| Ap. | Apothecary. |

The total initials required as indicating medical qualifications would then be only four in number:—

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| ALREADY ADMITTED. |                                                                    |
| M.D.              | } Signifying University Graduates, without specifying particulars. |
| M.B.              |                                                                    |

|                       |                                                                         |
|-----------------------|-------------------------------------------------------------------------|
| PROPOSED TO BE ADDED. |                                                                         |
| Ph.                   | } Signifying Physician in like manner, without specifying particulars.  |
| Ap.                   |                                                                         |
|                       | } Signifying Apothecary in like manner, without specifying particulars. |

The General Medical Council hopes this simple proposal will meet with the approbation of the Secretary of State for War, as doing impartial justice to all parties, and removing the repeated complaints that have reached it on the subject, as explained in the former correspondence.

D. J. CORRIGAN, Chairman of Committee.  
Lt.-Gen. Sir E. LUGARD, K.C.B., Under Secretary of State for War.

Sir D. J. CORRIGAN then formally proposed, seconded by Dr. SMITH, the adoption of the report of the Committee.

Dr. PARKES considered there were several objections against the adoption of the report of the Committee. He did not think there was a single surgeon in the army who would care to put "apothecary" after his name; because the term "surgeon," as used in the army, always included a medical degree or licence. Whereas, under the proposal

surgeons' names, "Surgeon and Apothecary," "Surgeon and Physician," &c., leading people to suppose one qualification was superior to the other. He strongly objected to the introduction of the word "Apothecary" on the "Army List" on principle. The initials proposed for this word were AP., making it appear at first sight as if they were allied to a particular quadruped, only had forgotten the final e. Then, with regard to the initials PHN. instead of Phs., as now, he thought the substitution unwise. With the experience he had had with great questions of such an order as those now before them, of registration or education, he believed it would take at least eight years to settle, so that every member of the Council who was not of Carlyle's opinion that "silence is the first virtue of man," would have an opportunity of expressing his views upon the question of PHN. and Phs.—Fun and Phiz (laughter). And he should not be surprised if Sir Dominic Corrigan should one day set himself to write a comedy or a farce, bringing in as *dramatis personae* the members of the Council and the Under-Secretary of State for War. He hoped Sir Dominic would not press his motion, and with a view to obviate the difficulties before them, he would propose as an amendment, "That the Registrar acknowledge with thanks the receipt of Sir E. Lugard's letter, and inform him that on further consideration the Medical Council has decided not to urge the matter referred to in Sir Edward's letter on the attention of the Secretary of State for War."

Mr. SYME seconded this amendment.

Dr. SMITH thought there would be no more difficulty in adopting the initials proposed than such as K.G. or K.C. in other grades of society.

Dr. ANDREW WOOD did not think any surgeons would look upon the proposal very favourably, and instead of its being considered a boon, he feared they would turn round and say to the Council, why have you exposed us to such a thing?

Mr. COOPER and Mr. HARGRAVE would support the amendment, considering the statement of Dr. Parkes, who was so thoroughly conversant with the feelings of the medical officers of the army, entitled to great respect.

Sir DOMINIC CORRIGAN, in reply, observed that as the term surgeon included all denominations, so "Ph." would include, as a generic term, all other qualifications. He quite agreed with Mr. Syme that all medical qualifications should be abolished. This would at once place all medical officers in the army on an equality, and remove the existing jealousies. He did not at present intend, as Dr. Parkes suggested, to write either a comedy or a farce. He considered the Secretary of State for War and the Director-General entitled to too great respect to be thus ignominiously brought into print; but if, at any future time, he did think of writing one, he should probably introduce his friend Dr. Parkes as one of the principal characters (laughter). There was another part of Dr. Parkes's speech which he (Sir Dominic) considered the bitterest censure upon the Medical Department of the Army. The letters AP., he had said, would be distasteful to them, and that any letters signifying apothecary should be omitted. If the medical authorities of the army wished to conceal the appendage signifying apothecary, they need not use it; and if Dr. Parkes would take the trouble to refer to the report, he would see that it was left to the discretion of the surgeon himself. It was absurd to say that AP. looked like "ape," or that PHN. was "Phiz." On the same principle they might say that M.D. was madman, or C.B. cabman (laughter). The simple question was, in what manner were medical qualifications to be inserted? To that question the Committee considered that parties should be treated with equal justice.

The amendment of Dr. Parkes was then put and carried. The resolution of Sir D. J. Corrigan was therefore lost.

Amendment, moved by Dr. QUAIN; and seconded by Mr. HARGRAVE:—"That it be recommended to the Secretary of State, under the difficulties of adopt-

ing initials capable of indicating the qualifications possessed by all army surgeons, to omit all initials as indicating professional qualification."

This amendment was negatived.

The reports on "Visitations of Examinations" was next considered.

Dr. ALEX. WOOD said, with the indulgence of the Council he wished, prior to bringing forward his motion, to make a few observations. He would first congratulate the Council on the good which their first attempt at legislation in this important matter had already done, and what it was capable of doing. The result of the visitations of examinations by the Council were so far very satisfactory, and he was convinced of the success which would eventually crown their efforts, if they persevered in it. If he entertained the same opinion as Sir Dominic Corrigan, that it was useless for the Council to attempt to legislate in this matter, he should not vote for a Royal Commission, but for an act of Parliament, not to supercede the licensing bodies, which should possess the full powers they sought themselves. He hoped the Council would persevere in their exertions, as he was sure it would be the best refutation they could have against the report circulated as to their uselessness. It occurred to him that the Branch Councils should be requested to continue these visitations of examinations, as the reports of last year were highly satisfactory, although the Examiners had no tangible basis on which to work; and he suggested, as a more efficient mode of procedure in future, the Council should extract from these reports those parts in the examinations which might appear to them defective, and send them to the various licensing bodies, not as an injunction, but as a friendly measure, suggesting what might be found to them as improvements, and what might be considered weak points in their examinations. He felt certain there was not a single body represented at that table who would not be anxious, as far as possible, to comply with any suggestions the Council might choose to give them (hear). There were certain defects which ought to be dealt with seriously; but he would first give each licensing body the opportunity of amending their defects, and if they declined in any case to make the examinations what they should be, he would suggest some special action should be resorted to in the matter; but, as he had said, he would first exercise the power of *moral suasion*, which had proved its efficacy at many a hard fought battle at that table. He moved, "That the reports of the visitations of examinations be received and entered on the minutes."

Mr. SYME seconded the resolution.

Dr. ANDREW WOOD said—Last year Sir D. Corrigan moved a resolution, at which he was surprised, the effect of which would be to cripple the efficiency of their visitations; but he was thankful the members of that Council had, with one or two exceptions, discharged their duty to the best of their ability; and he did think it hard that Sir Dominic should bring forward a motion refusing payment to those who had done their duty in the Council at the very time he refused to perform those duties himself.

Sir DOMINIC CORRIGAN objected on the point of order to these remarks.

Dr. ANDREW WOOD regretted Sir Dominic was so thin-skinned. He did not appear to think other people were, when he was attacking them. He (Dr. Wood) thought the Council should come to some determination as to what was to be done with these reports, and what was expected from the visiting bodies relative thereto. He did not know what difficulty was experienced in England and Ireland, but in Scotland he knew much existed, as to the exact knowledge of what was to be expected from them. He had no doubt that in offering any suggestions to these bodies, they should be severely criticised; some would probably be characterised as reports which had gone into the whole matter, while others would be thought bald and useless. He trusted the profession would not judge from this year what would be done in future years on these visitations,

and he trusted they would be enabled, by instructions from this Council, as to what was to be expected of the visitors, to bring next year before the Council and the profession such reports as might redound to their credit. On a cursory glance at the present reports, he was much satisfied with them in a general point, but on a more minute examination he perceived some of the bodies had taken every trouble to give the exact returns, whilst others, he was sorry to say, had not taken any trouble or interest in the matter. It was his wish that a complete report of the preliminary as well as the professional Examinations should have been furnished to the Council, for their satisfaction and decision, and also for publicity, as they would then be in a better position to correct any errors or defects which might be represented to them. They would also, by looking into and examining each thoroughly, do away with the odium which was continually being cast upon some of these bodies, and by the furnishing of annual returns the manner some of the diplomas were granted would be seen into, and other defects remedied. Dr. Wood then alluded at length to some of the facts mentioned in the Scottish reports, and after a speech which occupied the greater portion of an hour (a full report of which our space forbids us to publish), he concluded by reading the following resolution:—

Moved by Dr. ANDREW WOOD, and seconded by Dr. THOMSON:—"That the visitations of the examinations, preliminary as well as professional, of the qualifying bodies, by the Branch Councils, or such of their members as they may depute, be continued during the ensuing year: That the reports of the visitors shall apply to every part of the examinations of each body, and shall include a statement of the facts observed, and of the opinions of the visitors as to the efficiency of the examinations, as also such remarks and suggestions on defects in them as circumstances may indicate: That the reports of the visitors be submitted in the first instance to the Branch Councils; and that hereafter the Branch Councils shall direct them to be printed and circulated confidentially amongst the members of the General Council, so that they may be in condition at the meeting of the General Council in 1867 to consider them maturely."

Mr. CESAR HAWKINS said they could not yet form any comparison between the reports, because those reports were all drawn up on different systems. Dr. Storrar and himself had sought to enforce that no one obtained a diploma who had not been subjected to examination at the College of Surgeons in England. Of course the Council could not be expected to throw out suggestions to the College of Physicians or any other body in particular, or the discussion on the matter would be interminable. He thought, to expedite affairs, the reports should be circulated amongst the various licensing bodies. The visitations, he contended, should certainly be on one system, or no definite conclusion would ever be arrived at. In fact he doubted whether examinations conducted by the Branch Councils would ever be satisfactory.

After some further remarks from Dr. ALDERSON, Dr. SHARPEY, Dr. THOMSON, Mr. COOPER, and Dr. PAGET, the motion for the insertion of the report on the minutes was unanimously agreed to.

Sir DOMINIC CORRIGAN then rose and proposed the following amendment to the motion of Dr. Andrew Wood, which was seconded by Dr. A. SMITH:—

"That visitation of examinations carried out by members of the General or Branch Medical Councils being a reciprocal visitation by the representatives of the several licensing bodies of one another's examinations, is faulty in principle, and therefore can never command confidence. That any visitation of examinations would be worthless which did not include every examination, inasmuch as partial visitation could only testify as to the actual examinations visited—necessarily a very small proportion—and be no evidence whatever of the character of the examinations not visited, the larger proportion; that visitation of every examination would be impracticable, inasmuch as,

in addition to preliminary examinations, there are annually about three thousand five hundred professional examinations in the United Kingdom for degrees or licences." He observed that his reasons for objecting to the resolution and for proposing the amendment might be divided under two heads—principle and practice—and that he would so consider them. His reasons for objecting to the course proposed of continuing a system of visitations by members of the Branch or General Council were these. It was universally admitted through the profession, and well known to the public, that our licensing bodies, nineteen in number, or some of them, permitted candidates to pass so lax an examination, both in general and professional subjects, that they were quite unfitted for the practice of their profession. The army and navy authorities have had such experience of this that they will not now admit any graduate or licentiate of medicine or surgery to be placed in charge of the lives of our soldiers or sailors without first examining him in both branches of education, general and professional, and this disgraceful and discreditable state of things arises, as I believe, and as I have over and over again stated, from the competition among the licensing bodies for the sale of diplomas, and this state, instead of being amended, appears to be growing worse, for in the report of the Navy Board, received within the last few days and printed in our minutes, the navy authorities inform us that more than one-half of those rejected were utterly ignorant of Latin, of the simplest rules of English composition, and some of them so ignorant of materia medica and the doses of medicine, that it would be unsafe to allow them to prescribe, and yet such persons have received their diplomas from one, and, in many instances, from two, in the Navy List, and in all in the Army List, from at least two of our licensing bodies (all of whom are represented here), and in this reproachful state of ignorance are let loose on the public, and are legally qualified to hold all civil appointments, prescribing for, and operating upon our poor in workhouse hospitals and dispensaries (hear). In this state of matters what is the remedy proposed? To institute a system of visitations. By whom? By the parties on their trial. The nineteen licensing bodies are all represented here. The representatives of those bodies acknowledge that the mode in which their examinations are conducted permits ignorance and insufficiency to pass through, that they are no longer considered a guarantee of sufficiency of education, that the important departments of the public service—the Army and Navy Boards—have refused any longer to acknowledge their licences. They are accused parties, and it is proposed by their representatives here to institute and continue a system of visitations with a view to their own amendment—to justify themselves in public opinion. To judge from some of the reports of visitations already before the Council, it would appear there was nothing to be amended, for it is stated in one of the Branch Council reports for March, 1866:—"In every case the visitors express themselves satisfied that no persons were improperly passed in the subjects, or parts of subjects, in which they were examined." Unfortunately the army and navy reports of examinations flatly contradict this. Take as an illustration the old unreformed House of Commons, when the whole people outside clamoured against its rotten and corrupt boroughs. Suppose the representatives of those boroughs were to meet in conclave, as this Council is now met, and pass a resolution that they would inspect one another, A inspecting B's borough, and B inspecting A's borough, and so on. Would such inspection and report command confidence? Surely not for one moment. If managers of badly conducted lunatic asylums, boards of guardians of ill-treated poor, unpaid magistrates accused of partiality or unfair administration, captains of emigrant ships accused of endangering the lives of their passengers by employing ignorant subordinates in the management of their ships, or ill-treating their passengers, would not the whole world without receive with derision reports of visitations made by themselves and to themselves in each respective case?

Sir D. proceeded to observe that the next objection to the course proposed in the resolution was the utter impossibility of carrying it out in practice. As returned on the minutes, there are in England, within the year, about 1700 examinations, in Scotland 1400, in Ireland 500; altogether about 3500. Suppose 500 visited, a number far beyond what could be visited, 3000 would still remain unvisited. The visitation of even 500 would give no security whatever as to the character of the remaining 3000 unvisited. To take a homely illustration from a basket of eggs: suppose 50 at the top were examined and reported, would that be any evidence of the state of soundness of the remaining 450? Surely not. Sir D. said he was once acting as a commissioner to inspect a lunatic asylum. At our visit the women were all arranged round the day-room with clean clothes, wristlets, warm stockings, and well cleaned shoes. He congratulated one of the most intelligent of them on their comforts and cleanly appearance. She looked at him from under her eyelids, and asked—"Are you a Royal Commissioner?" "I am," said he. "Then don't you go to be a fool to think we're fagged out this way every day." Examinations can be fagged out too. Within the last few months, at one of the licensing bodies, whose representative sits at this table, and one not the least loud in lauding visitations, a candidate was examined for his diploma, and obtained it last November, there being only two persons present, the President and the Secretary of the licensing body, the Secretary being the sole Examiner on all the subjects of examination, the time occupied being only half an hour. The following is an extract from the memorandum of the examination:—

"Examination at ———, on Friday, 3rd Nov., 1865, commencing at eleven o'clock, a.m., and lasting half an hour, conducted entirely orally by the Secretary, in the presence of the President, no other person being present."

The candidate came back with the good news, and the next (a natural) result was that a batch of eleven candidates flew away from Ireland to get their diplomas on the same easy terms.

Some one called out "name," on which Sir Dominic Corrigan observed that if the President or Council desired him to give the name of the licensing body he would give it, but at present it appeared to him to be the better course to withhold the name of both college and candidate, as the candidate might not desire to have it stated at present that he had his diploma on such an examination, and on the other hand the licensing body, it was not impossible, might have some justification to offer in reply, and the course he would therefore suggest, with the concurrence of the Council, is that he would forward to the licensing body a copy of the memorandum, and submit the correspondence to the General Council at its next meeting.

The Council assented to this, and Sir Dominic continued—Suppose a visitation took place on one day in a month, what security does that afford for the examinations on the other days of the month? Every morning after a visitation there may be an eleven o'clock a.m. examination, considerably adapted to the convenience of candidates, and of such there can be no cognizance.

Sir Dominic continued—The third point to which he desired to draw the attention of the Council was that the defect in the proposed visitations of examinations was in not applying the test where it ought to be applied—viz., to the result. The Army and Navy Board very properly tested by results. They did not send about visitors to be present at some examinations and then accept such reports as applicable to all. They very properly say, "We will not visit your examinations, but when you turn out a graduate as sufficiently educated in your opinion, we will test him by actual examination—that is, we will test the result not the process of manufacture." This is the common-sense view. If the Council be right in its present course of procedure, then the Army and Navy Board are wrong, and the Council should address a remonstrance to these public boards to abandon their present system of examining candidates, and

to adopt the alleged improvement of the mode of proceeding of the Council. Apply here again the test of common sense, supplied us by great public departments. Do the responsible authorities who desire to have efficient artillery, invulnerable armour plates, or fast ships, send inspectors to witness the process of manufacture, and then rely upon such visitation, or upon reports from the representatives of the firms that manufacture them? They do not; they test by results; they estimate as of no value all certificates as to care in manufacture. They bring the guns and armour plates to the range at Woolwich, and the ships to the measured mile. They test by results, and this result is the only one relied upon, whether the article to be tested is a gun, an armour plate, a ship, a sea captain, or a medical practitioner. The London University, an institution highly to be commended, and a precedent to be followed, holds this course; it tests by results—cares nothing as to where or how the education is acquired, but an efficient Board of Examiners, having no pecuniary interest in the payment for a diploma, tests by results, that is, by the competency of the candidates.

Here Dr. QUAIN interrupted to ask how this test was to be carried out by the General Medical Council.

Sir D. CORRIGAN observed in reply that he was much indebted to Dr. Quain for the interruption, and complimented by it, inasmuch as it showed that the great intellect of Dr. Quain ran in the same groove as his own, for his finger at the moment was on the next memorandum of his notes—viz., how testing by results was to be carried out. The mode he proposed was this—to give up altogether the visitation of examinations, liable to so many fallacies, and to substitute for it a Board of Examiners for each branch of the United Kingdom, open to all graduates who shall have obtained degrees or licences. It appeared to him that if it be allowable under Clause XVIII. to depute and pay persons for visitations of examinations with the object of testing their efficiency, it would be equally allowable, under it and Section 20, to appoint and pay Examiners for giving the desired information to the Council as to the efficiency of examinations by testing results. It may be objected that such examination would not be compulsory, but neither are any of the rules or recommendations of the General Council on education or examinations, but it can scarcely be doubted that all well-educated graduates and licentiates would avail themselves of the opportunity of obtaining the "imprimature" of such a Board, while those who might be rejected would turn again to study to obtain it, and those who would not present themselves would labour under the disadvantage of not having a testimonium in addition to their licence or degree. The proposed plan would in no way interfere with the legal privileges attached to the diplomas of the several licensing bodies. The General Medical Council would also, under the proposed plan, gain the great advantage of substituting for visitation of examinations, subject to so many defects, the power of testing by results, which would be in accordance with the principles and practice in all similar instances outside this Council.

An amendment of Sir Dominic Corrigan having been put to the vote and negatived, the motion of Dr. Andrew Wood was agreed to.

It was then moved by Dr. STORRAR, seconded by Dr. ANDREW WOOD, and agreed to—"That the General Council meet to-morrow at one o'clock, instead of two."

Dr. EMBLETON presented the report of the Committee on Returns of Examinations and their results from the licensing bodies, and on the register of medical students for the last year.

The Returns of Examinations from the Medical Department of the Navy were next brought forward.

Dr. ANDREW WOOD wished to make a few observations before these reports were passed. He said the Council, the profession, and the licensing bodies were much indebted to the Navy Department for granting these returns, which unquestionably tended to bring out the fact that students had been passed, and their diplomas given them,

by the several licensing bodies on very indifferent grounds, and then, on re-examination before the Navy Board, they had no qualifications to warrant their acceptance in that department. He might be told they should not look at these returns as they stood, as the best men did not go there to be examined, but this was no excuse for the licensing bodies, though they might be aware such was the case. But it must be remembered that all those who had thus failed before the Navy Board had probably passed their examinations by the licensing bodies some four years since. He did not despair in the face of these returns, but believed that what was being done by the Council would be brought to bear upon the licensing bodies, and he hoped three or four years hence similar returns might be laid before them, that they might see what progress was being made, and he trusted then they would have the satisfaction of knowing they had done their duty. He begged leave to propose the following resolution:—"That the Director-General of the Navy Department be respectfully requested to furnish in future the Council with copies of questions proposed to candidates for Navy Medical Commissions, in the same way as is done by the authorities of the Army Medical Department."

Dr. FLEMING seconded the resolution.

Dr. ALEXANDER WOOD had no objection to the proposal of Dr. Andrew Wood, but wished to make a few remarks, as he had noticed that year after year they had been sliding into a very dangerous position with regard to this matter. They had received these returns, and entered them on their minutes, as though it were possible to apply them as a test to the efficiency of the licensing bodies. Every one knew, who had had any experience with examinations, that much depended upon the way questions were put, and this in a great measure would account for some candidates passing the licensing bodies that were refused by the Navy Board. True, some examinations were more stringent than others, and he thought, in many cases when Examiners got old, they were not so strict as before, but he considered great improvements were gradually and surely making headway in this important matter. At least he could answer for the body to which he belonged.

Dr. PARKES believed much good had been done by these returns being furnished. At the same time he felt bound to say that neither the Army or the Navy Boards would hardly be justified in furnishing these returns in future to the Council, though they were of the greatest value, if they were to be made the means of attacking gentlemen who entered into the service.

Sir DOMINIC CORRIGAN had listened with pain to the discussion. As long back as May, 1864, these returns were unanimously asked for, but he was sorry to see, now the request had in some measure been complied with, certain members of the Council were disposed to throw cold water upon them and disparage their utility. If this discussion reached the ears of those gentlemen who had so kindly furnished these returns, he feared their issue would in future be stopped. He held these returns to be of the greatest possible value, and as they were meant as a test to the various licensing bodies, they should be so applied.

Mr. CESAR HAWKINS reminded the Council that students who had this year applied for examination had probably never been before examined by any body, and therefore it was no fault of the Council. Allowance must also be made for the memories of candidates, and it was not at all unreasonable to suppose that sometimes men forgot some of the things they had learned several years before. The returns were of very little value unless they had the examination papers.

Dr. PAGET considered it would be a great mistake if the furnishing of these returns should be interrupted. Although it was not a crucial test, yet it was a test or thing produced, and he conceived it was much better to judge of quality than it was of the process by which it was produced.

After a few remarks from Professor SYME and from Dr.

ANDREW WOOD in furtherance of the resolution, the same was put and carried unanimously.

A similar motion to the authorities of the Army Medical Department was then proposed by Dr. ANDREW WOOD, and seconded by Dr. PARKES, which was also carried.

The following report of the Finance Committee was then agreed to:—

"The Finance Committee beg leave to present, in a tabular form, a statement of the estimated and actual income and expenditure of the year 1865; also an estimate of the income from ordinary sources, and of the expenditure, as far as the Committee are able to judge, for the year 1866.

"From the figures in the table it will appear that the actual income of the past year fell somewhat short of the estimate, but as, on the other hand, the actual expenditure is less than what was estimated, there is a small balance in favour of the Council.

"In reference to these estimates, the Committee have to observe that it is scarcely possible to judge of the prospective expenditure with any near approach to accuracy, inasmuch as the amount is greatly dependent on the duration of the sessions of Council, which cannot, with certainty, be determined beforehand.

"A statement of the receipts and disbursements on account of the British Pharmacopœia, since the date of the account presented last year, and of the balance in the Bank at the credit of the General Council, is given up to January, 1866. "W. SHARPEY, Chairman."

The report of the Committee on Returns from the Licensing Bodies was next considered and adopted; as were also some additions to the standing orders, proposed by Dr. Alexander Wood.

Dr. FLEMING moved, in pursuance of notice:—"That the Executive Committee for the ensuing year consist of ix members, exclusive of the President, instead of four, as at present; that of the six to be elected, four be chosen from the English, one from the Scotch, and one from the Irish Branch Councils."

A long discussion on this motion arose, in which Drs. PAGET, ALEXANDER WOOD, SYME, SMITH and SHARPEY took a prominent part; but as this would not interest our readers, we merely quote the President's opinion on the subject in reply to the request of Dr. Fleming for same.

The PRESIDENT said—So long as the Executive Committee was composed of members of the English Branch Councils exclusively, the General Council ought to be jealous of delegating greater powers to it than it at present possessed. But if any means could be adopted by which they could get a fair representation on that Committee of the other Branch Councils, he thought further powers might be entrusted to it according to the Act of Parliament, and that such an Executive Committee might be able most materially to lighten the labours and shorten the sittings of the Council. If they asked his opinion as their President, he must say that he thought one of the great defects in their organization was that they had no means of carrying on business except through the large body sitting round that table. A great deal of the preparation of business which came before that Council might be transacted by the Committee proposed, and, therefore, he thought it would certainly be a step in the right direction if such a Committee were appointed.

A ballot of the whole Council was then taken for the Executive Committee for the ensuing year, when the following members were declared to be elected:—

|                           |                            |
|---------------------------|----------------------------|
| Mr. C. Hawkins, 17 votes. | Dr. Andrew Wood, 12 votes. |
| Dr. Sharpey, 17 "         | Dr. Acland, 8 "            |
| Dr. Paget, 13 "           | Dr. A. Smith, 8 "          |

Dr. ANDREW WOOD, in rising to propose a motion, said that he thought it would not be then inopportune to make a few remarks relative to the new Medical Acts Bill, and what had been done to bring it before the Government. The Council had hoped ere this to have received some communication on the subject from the Government. Mr. Ouvry (their solicitor) had seen Sir G. Grey's

private Secretary, and impressed upon him the importance of receiving a deputation from this Council during the present session, but no communication had up to that time come to hand. It was quite clear the Council, having prepared the Bill, ought not to separate without taking the proper steps for seeing that it was pressed upon the Government, and therefore he begged to propose this resolution:—"That it be delegated to the Executive Committee to confer with the Government in regard to the proposed Bill for the amendment of the Medical Acts, to press on the Government the expediency of its being adopted as a *Government measure*, and to take all necessary steps for aiding the passing of the Bill through Parliament."

The desirability of its being introduced as a *Government measure only*, having been urged by Sir D. Corrigan, words to that effect were then embodied in Dr. Wood's motion, and the same was put and carried.

The remainder of the business on the programme having been disposed of, it was resolved:—"That the thanks of the Council are due, and are hereby tendered to the Treasurers, Dr. Quain and Dr. Sharpey, for their important services."

On the motion of Dr. ANDREW WOOD, seconded by Dr. STORRAR, it was agreed:—"That the thanks of this Council are eminently due, and are hereby offered to the Royal College of Physicians, London, for their obliging and courteous accommodation during the present session of the Medical Council."

A gratuity of twenty guineas was then voted to the resident officials of the College of Physicians for services rendered to the Council.

A gratuity of twenty guineas each to Mr. Bell and Mr. Roope, the clerks of the Council, in consideration of their extra services during the present session, and extra work consequent on the registration of medical students—a duty which was not contemplated at the time that Mr. Bell and Mr. Roope were appointed.

It was further resolved:—"That the cordial thanks of this Council are due, and are hereby tendered to Dr. Andrew Wood, for his unwearied exertions and invaluable services as Chairman of the Business Committee during the past and present sessions of the Council."

The last motion was then proposed by Dr. ANDREW WOOD, seconded by Mr. HARGRAVE, and cordially agreed to:—"That the thanks of this Council are tendered to the President, for his kind, courteous, and efficient services during the present session of the General Medical Council."

This concluded the session of the Medical Council for 1866, and the meeting broke up about seven p.m., having sat this day six hours.

## Reviews.

ON THE MERCURIAL AND NON-MERCURIAL TREATMENT OF SYPHILIS. By R. WILLIAM DUNN Surgeon to the Farringdon Dispensary, &c. London Hardwicke. 1866. Pp 48.

THE author of this *brochure* informs us in his preface, that his object is to lay before his medical brethren a *résumé* of the views of different writers on syphilis, upon the mooted question of whether the disease should be treated with or without mercury. He himself, he adds, is now from experience, having tried both methods, in favour of the latter or non-mercurial method. An abstract of the paper was read at the Medical Society. After glancing at the opinions of Ambrose Paré, who mentioned that in his time, 1649, the advocates, of mercury were, as now, opposed by the partisans of guaiacum, &c., he shows how John Hunter considered that if there was such a thing as a specific, mercury was one for the venereal disease. He refers to the great crusade against mercury which ensued at the commencement of the nineteenth century, and how the non-mercurial plan was advocated by

the Royal Council of Health of Sweden, by Fricke, Duvergie, Kayser, Rapatel, Desruelles, Judd, Hennen, Fergusson, Guthrie, and others, and that the *Medico-Chirurgical Review* had stated that 80,000 cases had been tried from 1800 to 1835 inclusive without mercury, and that the treatment had succeeded better than the classical treatment. On the other hand, the mercurial treatment of the disease had for advocates Carmichael, Wallace, Dupuytren, Brodie, Abenethy, and many other eminent surgeons. The report of the Army Board, dated April 2nd, 1819, gave 1940 cases of ulceration of the genitals treated without mercury: 96 cases of secondary symptoms; 60 ulcers treated by Dease without mercury, had 6 cases of secondary disease; 40 cases treated by Judd had 7 cases of secondaries; 100 cases treated by Green gave 9 cases of secondary disease. Fricke discovered that the disease was cured more rapidly without mercury, and that relapses were less frequent and slighter. 407 cases of primary sore treated by Hennen had 46 cases of secondary symptoms. Boeck stated that 3123 persons were treated by mercury, 1036 had relapses; 280 without mercury, 82 only had return of the disease. Samuel Cooper, writing in 1825, describes the dreadful mutilations caused at Bartholomew's Hospital by the salivations employed there. Among mercurialists of the present time our author mentions the names of Ricord, Cazenave, Acton, Lee, Brodie, de Méric, Erichsen, Hamilton, and others. Sir B. Brodie said that there was no remedy capable of extinguishing the venereal poison like mercury. Mr. H. Lee says that mercury delays the appearance of secondary affections. Mr. Erichsen says he has seen the non-mercurial plan extensively tried, and believes that secondary symptoms are not so frequent when mercury is used. He also says that some of the worst forms of the disease he has ever seen has occurred in persons who have not taken mercury; when given to healthy constitutions he says it will generally prevent secondary disease. Professor Miller says that although usually mercury is not required some cases cannot be well treated without it. Müller (of Vienna) and Cazenave hold similar opinions, as also Sir Charles Bell. He thinks that there is no senior in the profession who would be so unnatural as to treat a syphilitic sore without mercury. Mr. H. Lee says that papular and scaly disease are the most common form of disease after the treatment of the primary sore by local means, whilst pustular and tubercular forms are most common after mercury; the author considers this damaging to the advocates of mercury. Mr. Guthrie considers it proved that all ulcers of the genitals will get well without mercury. Mr. Green considered that every form of the disease except iritis could be better cured without mercury than with it. Our author informs us that Dr. Drysdale, himself, and others have successfully treated syphilitic iritis without mercury. Baerensprung says that mercury deteriorates the constitution, and that the disease is far better treated without it. Diday accuses mercury with causing phagedæna in some cases, stomatitis, dyspepsia, trembling of the extremities, apoplexy, and insanity, even when treated by Ricord and other masters of the mercurial art.

Professor Syme advises abstaining altogether from mercury in secondary symptoms, and says that affections of the periosteum or bones never occur in a severe form except when the patient has suffered from mercurial influence. Dr. Fricke says that affections of the bones and periosteum are frequent in syphilitic persons; but caries or destruction of the bone are seldom or ever observed except when mercury has been administered. Weeden Cooke says that once the secondary eruption has been gone through, it generally does not relapse when no mercury is given, except in persons who drink or smoke much. He likens the disease to an exanthem, and thinks that the eruption should not be kept back by the lowering influence of mercury. Dr. Drysdale

says that severe cases, even if they may occasionally occur under careful hygienic treatment, are remarkably rare; but even were they common, it would be no argument for so poisonous a substance as mercury is well known to be. He contends that the disease, in general, when hygienically treated, is by no means severe, and that tertiary affections alone require iodide of potassium, whilst all other symptoms may be cured by attention to general diet and external applications, caustics, &c.

The author believes that mercury is never required internally in the treatment; and he recommends an analeptic plan of treatment, with iodide of potassium in periostitis and nodes. He says that he has now treated upwards of forty cases of primary syphilis without mercury, and the secondary eruptions also without mercury, and none of these had relapsed. He states in common with Dr. Bennett that rupia scarcely ever occurs in persons who have been treated simply, whilst it is by no means uncommon when mercury is used. The same holds good for bone disease.

A few cases with the details of their treatment are added by the author, exemplifying the mode of mercurial and non-mercurial treatment used by him before and after he became aware of the superior efficacy of the latter method. One of the cases shows how indurated chancres gradually heal up and become soft again under water-dressing alone. One of the most interesting portions of this work is the information given concerning the treatment of infantile and hereditary syphilis. M. Cullerier says that a syphilitic infant not treated by mercury always dies within a given period. Mr. Eriksen considers that mercury is a specific in such cases. The author mentions that Mr. Allingham, Dr. Drysdale, Dr. Boeck, Mr. Cooke, and himself, have found that, when hereditary or infantile syphilis is treated without mercury, the rate of mortality is much lower than when mercury is used. Mr. Allingham's cases gave 48 cases treated, with 6 deaths, whereas the mercurial treatment appears to present 29 per cent. of deaths. The author concludes that primary sores can be healed without mercury; that mercury does not prevent secondary symptoms; and that when secondary symptoms appear in simple treatment, they are milder than when mercury is used—*e.g.*, rupia and bone disease very rarely following the simple treatment; and that infantile syphilis is better treated without mercury than with it.

Whether the reader agree or not with Mr. Dunn's conclusions, he will not, we believe, find fault with that gentleman for not stating his adversary's cases fairly. There is no attempt made by him to shirk the evidence of mercurialists, and we therefore recommend this *brochure* to the attention of the profession.

#### LIST OF ENTRIES IN THE LOCAL REGISTER BRANCH MEDICAL COUNCIL (IRELAND), FOR THE MONTH OF APRIL, 1866.

- Dwyer, Peter Joseph, county Cork, L.A.H.D. 1863.  
Harvey, Charles Albert, Manchester, L.R.C.S.I. 1865,  
L.R.C.P.Edin. 1865.  
Turner, J. Eaton, Tuam, L.R.C.P.Edin. 1866, L.R.C.S.Ed.  
1866.  
Kelly, John Bellew, Drogheda, L.R.C.S.I. 1865, L. 1866 and  
L. Mid. 1866, K.Q.C.P.I.  
Doyle, Bernard, county Down, L.R.C.S.Ed. 1865.  
O'Grady, Michael, Dublin, M.R.C.S.Eng. 1844.  
Evans, Joshua William, Dublin, M.B. Univ. Dub. 1864,  
L.A.H.Dub. 1866.  
Harman, Wm. Morton, county Cavan, M.B.Univ. Dub.  
1866, L.R.C.S.I. 1866.  
McAlister, James, Galway, M.B.Univ. Glasg. 1865, Mast.  
Surg. Univ. Glasg. 1865.  
Murray, William, county Westmeath, L.R.C.P.Edin. 1866,  
L.R.C.S.Edin. 1866.

THE returns of the cattle plague show but a very small decrease.

"SALUS POPULI SUPREMA LEX"

WEDNESDAY, JUNE 6, 1866.

### THE VISITATION OF EXAMINATIONS BY THE MEDICAL COUNCIL.

By the 18th Clause of the Medical Act of 1858, power is given to any member or members of the General Council, or any person or persons deputed by the Council, to attend and be present at the examinations held by the different Medical Licensing and Examining Bodies; the object, of course, being to keep the Council in possession of information as to the method of examination adopted, and the standard of knowledge required of the candidates. There has hitherto been very great difficulty in carrying out a system of supervision of examinations, and the causes of the difficulty are obvious enough; one is, that no funds are specifically provided for the purpose; and another is, that nearly all the members of the Council are themselves examiners or teachers, or are otherwise closely connected with the examining bodies. From the want of funds it has been found impossible, we presume, to delegate this duty of supervision to persons out of the Council, and the second circumstance had made the task alluded to one of peculiar delicacy. Nevertheless, the Council at length determined that an effort should be made, and in April of last year it was resolved that members of the Council, deputed by the Council itself or one of its branches, should visit the examinations conducted by the qualifying bodies in the United Kingdom, and report the result of their observations to the General Council.

This resolution has been carried into effect, and the Branch Council representing each division of the United Kingdom, has divided among its members the duty delegated to it, and the reports have just been printed. As every member of the profession is interested more or less in the subject, inasmuch as nearly every one has passed one or more of the examinations himself, we make no apology for alluding to the subject in some detail, and publishing some portions of the reports themselves.

Although reports have been received from each of the three divisions of the United Kingdom, we must limit ourselves at present to that which has emanated from the Branch Council for England. The examinations attended by the delegates of this Branch, include those of the Royal College of Physicians of London; the two examinations (first and second) for the diploma of the Royal College of Surgeons of England; the first and second examinations for the licence of the London Society of Apothecaries; the first and second examinations for the degree of M.B. at Oxford and Cambridge, and that which at Cambridge must be passed in addition for the degree of Master of Surgery; and the final examination for the degree of M.B. of the University of London.

Now, it will not excite much surprise when we state that the visitors express themselves generally as being satisfied with the manner in which the duties are performed at these various bodies, but they very properly suggest some points in which the examinations of some of them are capable of improvement.

Those who are practically acquainted with the subject of examinations must perceive at a glance that the six bodies just mentioned are placed, in respect to Medical Education and Examination, in the most different positions. The Universities of Oxford and Cambridge for instance, are ancient and amply endowed foundations, in which, however, medicine, though most ably taught and cultivated, holds a comparatively inconspicuous place; the University of London has no school whatever, and being endowed by Parliamentary grants, is enabled to conduct its examinations with the most perfect independence, and, we may add, completeness. The College of Surgeons depends almost entirely for its revenues and the payment of its officials on the fees obtained by candidates for the diplomas—a most unfortunate arrangement, although we by no means assert that it leads to corrupt practices, and the examinations at Apothecaries' Hall, for which a very moderate sum is demanded, are conducted by examiners, who, like those of the College of Surgeons, are paid from the fees of the candidates who are passed. At the College of Surgeons, however, the fees being large, the revenues are considerable, and indeed support nearly the whole expenses of the College. At Apothecaries' Hall, the fees are small, and barely suffice to pay the necessary expenses of the examinations. Now it is at the outset unfair to institute a strict comparison between the proceedings of richly endowed and independent bodies like the Universities of Oxford, Cambridge, and London, and those of bodies which, like the College of Surgeons and Apothecaries' Hall, depend, entirely, so far as their examinations go, on the students fees. We repeat that this is a very objectionable arrangement, but we must take matters as we find them. Again, the Universities of Oxford, Cambridge, and London, hold their medical examinations *once a year*, and can, of course, provide themselves amply with all necessary resources. The College of Physicians holds its examinations at monthly or trimestrial intervals. The College of Surgeons holds its examinations at certain fixed periods during the year; and the Court of Examiners of the Apothecaries' Society is compelled by Act of Parliament to sit *once a week*, whether there are any candidates or not.

Now it is perfectly preposterous to expect that twelve men, such as the Examiners of the Society of Apothecaries, being paid a very small sum, and compelled to sit once a week, can devote so much time and attention to the examination of the candidates as the Examiners of the Universities of Oxford, Cambridge, and London, who are amply paid for attending to examine two or three times a year; and we may add, it is preposterous to imagine that a host of young men, such as are necessarily sent out every week to practise on board ship, or in

country districts, or in poor neighbourhoods, or as Union Surgeons, can have or indeed require to have, the same amount of classical, general, and scientific, in addition to strictly medical education, as the Graduates of Oxford, Cambridge, or London, in the two former of which Universities it is almost impossible for a candidate to take a degree till he is twenty-three or twenty-four years old, and in the last (the University of London) the examinations are so numerous and so stringent, that although a candidate *may* pass and obtain a degree at twenty-one years of age, such cases are very rare. But such are the exigencies of the public service, and such, we may add, are the pecuniary necessities of many of those who are entering the Medical Profession, that it is impossible for them to do more than obtain a respectable diploma at twenty-one years of age, and then to support themselves either as assistants or in practising among the poor, or in the army and navy.

We are not offering these remarks by way of apologising for the shortcomings of the London Society of Apothecaries, because in fact they require no apology on our part, and the Visitors of Examinations expressly state that this body has been steadily doing its best to raise the standard of education among the General Practitioners: and it is a well known fact (although the Visitors do not allude to it) that, in point of preliminary education, this Society instituted a compulsory examination in Greek, Latin, and Mathematics, long before the Medical Council was appointed or even thought of.

The same considerations scarcely apply to the College of Surgeons of England. It cannot be said with truth that this body has advanced with the improvements of the present age; and although we hesitate to impute corrupt or unworthy motives, we may state as a fact that this College for a long time studiously ignored the necessity of preliminary education on the part of its candidates, and thus obstructed the efforts of other examining bodies which were striving in the opposite direction. Since the passing of the Medical Act, indeed, the College has been morally, if not legally, compelled to obey the regulations of the Medical Council in this and other respects; but with the great resources of this College and the high reputation which it holds in public estimation, we consider that it has fallen far short of the duties it owes to the Medical Profession.

#### THE GENERAL MEDICAL COUNCIL.

In the remarks we made at the commencement of the sittings of the Medical Council for the session, we believe that we were not very far wrong in our misgivings as to any efficient measure being passed for the benefit of the Profession in the present year. At the time when we are writing, the Government has given no pledge that it will introduce the amended Medical Reform Bill into Parliament, and the fate of the measure is left to the chance of its being adopted by some independent member of the Legislature. We are also left in uncertainty whether the Government will adopt the amendments.

proposed by the Medical Council. It will be recollected that the insidious introduction of the words "Doctor of Medicine" instead of "Doctor" in the 40th clause, on the part of the Government, is entirely subversive of the intentions of the framers of the amended Bill, and, if allowed to remain, will render the measure entirely nugatory as a protection to the public against quacks and impostors. The Pharmacopœia also appears to make very slow progress, and it may be many months before the new edition sees the light. We are aware of the many difficulties with which the Medical Council has to contend, and we make the foregoing remarks without any wish to disparage its labours, but merely to put the matter in a true light before the Profession.

#### THE NEW CHEMICAL NOTATION.

A NEW, and somewhat unexpected, and rather formidable difficulty has just occurred in the preparation of the new Pharmacopœia. It will be recollected that the Pharmacopœia as it now exists, although not overloaded with chemical technicalities, contains a notation of chemical substances such as has been for many years taught in the schools of chemistry. Very lately, however, several distinguished chemists have come to the conclusion that the existing notation should be changed, owing to some very cogent theoretical considerations, connected with the relative size of the atoms of oxygen and hydrogen, and consequently of the other chemical elements. The practical effect of this change is very unfortunate, and is almost equivalent to a reform of the alphabet, which is allowed to remain in its present state, not because it is theoretically perfect, but because European nations have become accustomed to its use. People who have learned chemistry under the old notation are or will be obliged to adopt the new one, and although this is no great hardship to men of science, it will be found very inconvenient to those who are beginning the study, or have with some difficulty mastered the intricacies of the present system. After considerable discussion, it has been determined by the Medical Council that in the new Pharmacopœia, both systems of notation shall be adopted, although it was the opinion of some practical persons that it would be better, under the circumstances, to omit all chemical symbols whatever.

#### QUANTITY VERSUS QUALITY.—THE CORK BOARD OF POOR-LAW GUARDIANS AND THEIR MEDICAL OFFICERS.

It has occasionally been our unpleasant duty to bring the conduct of the Cork Board of Poor-law Guardians, or of some obstinately ignorant members of that inglorious Corporation, under the notice of the profession; and we have reason to believe that our remarks have not been without effect on that pachydermatous body, which, according to the well known aphorism of DANIEL O'CONNELL, "has no conscience." On the present occasion we have—with great regret—to parade that same board before the tribunal of educated public opinion, in

the hope that the criticism to which they will be thus subjected may do them wholesome service and benefit suffering humanity, whether in the shape of a sick pauper, or of a careworn and worried workhouse physician.

In another column we give our readers the benefit of perusing a leading article on the subject from the *Cork Examiner* of the 28th ult., which has been forwarded to us probably by one of our subscribers. We heartily endorse every opinion therein expressed; and we affirm, that were leading articles in the daily papers on matters connected with our profession written in the fair and educated spirit which throughout marks this one, it would be well for our country and for its best interests. It is fair to add that the *Cork Daily Reporter* of the 31st ultimo has also taken the right side in a temperate article which we have read with great pleasure.

It seems that the Cork Workhouse is a very large institution; so large that there is hospital accommodation for about 1200 in it. Beside a Resident Surgeon, there are two Visiting-Physicians, to whom the medical affairs of the Workhouse are confided—Dr. POPHAM and Dr. W. C. TOWNSEND. Both these gentlemen not only hold a high professional position in their own city, but are well and favourably known to the profession very far beyond the local limits of their practice. Under their management the popular opinion regarding workhouse hospital treatment has been completely reversed. Instead of avoiding the institution under their care as "that bourne from which no traveller has returned," the poor, and the sick artisans, rush to it with trustful eagerness; and, it is said, that the percentage of deaths is less there than in any other hospital of the kind in Ireland.

But it has become necessary to erect a Fever Hospital in addition to their previously existing medical institutions; and the Cork Board have actually had the barefaced and inhuman hardihood to require their two medical officers, not only to attend the present hospitals, but also the new Fever Hospital, when opened; and they prescribe that the physicians shall attend at least three hours a day, of which half an hour is to be at night.

From the *Cork Examiner* of the 30th ult. it appears that there are at least three members of this Board who claim to be members of our profession, and who play the P.L.G. or the M.D. just as it suits them. Of one of them it was stated at the Board meeting of last Wednesday that he had not been seen in an hospital for thirty years; and another is not favourably known to our readers in connection with subjects of this kind in days gone by. Not one of these gentlemen appears to have protested in any way against the vote of the majority. It appears, however, from the *Cork Constitution* of the 31st ult., that Dr. Morrogh, another guardian, did honourably protest against the decision of his fellows. With rare exceptions, these Medico-Guardians are a nuisance to the profession; and, because a little learning is a dangerous thing, they are a curse to the poor.

There is something so perfectly monstrous and so hopelessly ignorant in this Cork mandamus, that there is little or no use in arguing the question with men who are deficient in the first principles of reasoning, and who thus prove themselves to be utterly unfit for the position, which, unfortunately for the poor, the law allows them, of prescribing rules for men whose professional principles and modes of practice they know nothing at all about. JOHN LOCKE may, or may not have been right, when he asserted the non-existence of an innate idea, urging that the human mind is like a piece of blank paper. The Cork Board of Guardians certainly have no idea innate, or acquired by experience, in this case; and the only dispute about them is as to the kind of paper to which their minds may be likened. Some may say it is coarse brown; others may affirm it to be blotting paper, whited brown, or thick cream-laid note; but we do not see that any valid objection can be made to our opinion that it is *foolscap*. The leading article from the *Cork Examiner*, to which we have referred, very ably puts the question in a popular view, showing that what the Board want is to carry into effect the vulgar and ignorant notion of quantity *versus* quality. We hope that the Poor-law Commissioners will promptly refuse their sanction to this inhuman and impolitic ukase of the Cork Board. The son of Sirach wisely said, in olden time, "Honour a Physician with the honour due unto him for the uses which ye may have of him;" but here we are reminded of one of the saddest truths uttered by the wisest of Kings, "the tender mercies of the wicked are cruel."

THE anniversary field day of the Profession in Ireland took place on last Monday. The first Monday in June is the day named in the charter for the election of the President and Council of the Royal College of Surgeons in Ireland, and as that event usually attracts a large number of the provincial Fellows of the College, the opportunity is taken to hold the annual meetings of the Irish Medical Association and the Royal Medical Benevolent Fund Society of Ireland, and the day is celebrated by the banquet of the Medical Association, which is looked forward to with much interest as a reunion of provincial and metropolitan members of the Profession.

The election of the Council of the Royal College of Surgeons has this year excited much interest, in consequence of the candidature for the first time of two claimants, who have energetically contested the position with the outgoing Council, who have presented themselves for re-election. The President, Mr. WILMOT, sought to be instated in the vacancy caused by the elevation of Mr. BANON to the Vice-Presidency, and as this course has hitherto been almost always adopted, and as the remaining eighteen Councillors have solicited the suffrages of the Fellows, it will be perceived that the new candidates presented themselves without any actual vacancy, and contested the election with the entire of the ex-Council. This contest was, however, *de facto*

confined to a few of the junior and less influential members and to the outgoing President, Mr. WILMOT, whose return was considered as almost certain. The new candidates who offered themselves were Dr. DENHAM, the Master of the Rotundo Lying-in Hospital, and occupying the official leadership of the Obstetrical Profession in Ireland. Dr. DENHAM, as we understand, simply offered himself to the electors without pressing his claims on them, and had there been a vacancy he would, without doubt, have been accepted *nem. dis.*, on consideration of his very paramount qualities, not less than his deservedly high official standing. The other candidate was Dr. EDWARD DILLON MAPOTHER, Professor of Hygiene in the College, and Public Officer of Health for the City of Dublin. Dr. MAPOTHER has gained for himself a very leading public position in connection with Sanitary Science, and is well and favourably known to our readers as a talented and laborious worker, more especially in this department of the Profession. Dr. MAPOTHER's candidature was vigorously supported by a considerable number of the Fellows of a more junior standing, and would have probably been well received by the great majority of the electors had there been an opening for his election in the death or resignation of any of the existing Council. A large number of the Fellows, however, supported the ex-Council against all comers, and declined to substitute Dr. MAPOTHER's name for that of any member, on the ground that the existing Council had worked for the College and the Profession well, truly, and harmoniously, and that it was inexpedient, without very strong reason, to break up so efficient a body. The contest has resulted in the election of Dr. MAPOTHER to the Council, and the return of Mr. WILMOT, the ex-President, to the vacancy created by Mr. BANON's election to the Vice Chair.

#### A PERMANENT MASS FOR PILULA FERRI IODIDI.

IODIDE of iron being so unstable when exposed to air, Mr. Gross proposes the following form for a permanent pill-mass, which may be prepared extemporaneously:—

|                               |            |
|-------------------------------|------------|
| Iodine . . . . .              | 40 grains. |
| Reduced iron,                 |            |
| Powdered acacia,—aa . . . . . | 10 "       |
| Powdered sugar . . . . .      | 20 "       |
| Glycerine . . . . .           | 15 drops.  |
| Powdered althæa . . . . .     | q. s.      |

To be made into 50 pills.

Triturate the iodine and the iron thoroughly together, dry, until they are reduced to a fine powder; then add the glycerine, and rub till the fumes of iodine cease to be given off, and the mixture assumes a greenish colour. Then add the acacia and sugar, and lastly, sufficient powdered althæa to bring to a pilular consistence.

The mass should be very stiff. When the pills are formed roll them in *ferri pulv.*, and then coat them with *tolu.*—*Year-Book of Pharmacy.*

ANÆSTHESIA BY PULVERIZED ETHER.—An article has appeared in the *Gazette Hebdomadaire* of Paris (March 23), wherein M. Léon Le Fort tries to prove that this practice is borrowed from the French. He relies on a passage of the article "Anæsthesia," by M. Giraldés, in the now publishing "Dictionnaire de Médecine et de Chirurgie Pratique." M. Giraldés says:—"I think that ether or chloroform, pulverized by any of the numerous well-known instruments, especially by Luer's, may yield good results."

TWENTY-FOURTH ANNUAL REPORT  
OF THE  
ROYAL MEDICAL BENEVOLENT FUND  
SOCIETY OF IRELAND.

It is with great pleasure the Central Committee of the Royal Medical Benevolent Fund Society present their Twenty-fourth Annual Report to the subscribers and friends of the institution.

Whilst the experience of another year demonstrates the increasing utility of the Fund, and adds to the number of those who have reason to thank God for its existence, still the record of the past twelve months shows some losses and disappointments. Happily these are not of such a nature as to affect the stability of our Society. Having alluded to them, however, it may be as well to mention what they are before proceeding further. We have to lament the removal by death of two members of the Central Committee, Dr. Edward Hutton of this city, and Dr. Richard Corbett, Honorary Secretary and Treasurer of the Cork Branch. The Committee feel that more than a passing mention of his name and office is due to the memory of this latter gentleman. They cannot but regard his death as a serious loss to the Society; for his attachment to it was deep and sincere, whilst his zeal and activity in its service were untiring. Even when confined to his dying bed, Dr. Corbett's solicitude for the welfare of the Society, and his watchful regard to its interests were unabated. One of the last letters he ever wrote was addressed to Dr. Harvey, the esteemed President of the Cork Branch, urging him to convene an early meeting of the Local Committee, to accept his "regretted resignation," and to appoint some one in his place, "that the Society might not suffer through any delay or neglect on his part." He concludes the letter by saying, "I hope my successor will be able to do much more than I have done for my pet Society." None of us can refuse to join in this hope, vain though it may appear; at the same time we feel convinced that Dr. Gregg, who has undertaken the duties of Honorary Secretary and Treasurer of this important Branch, will prove himself, in every way, a worthy successor of Dr. Richard Corbett.

The Committee have further to report that the legacies of Mr. Carmichael and Dr. Colvan, the former of £4,500, and the latter of £500, are still unpaid. This announcement will doubtless occasion disappointment, but the Committee are assured that the ultimate acquisition to the Society of the Carmichael bequest is certain; the delay in its payment arising merely from the administration of the will having been placed under the Court of Chancery. As regards the Colvan legacy, the case is different. Here the validity of the will is disputed by some of the testator's family, and till this point be decided we cannot know whether his benevolent intentions towards our Society will be carried into effect or not.

The Committee having learned that Dr. McDowell of Monaghan, had bequeathed a sum of £200 to the Society, they made the necessary inquiries respecting it. The personal estate, it seems, is insufficient to pay this and another charitable bequest (to the Protestant Orphan Society), and the case now waits the decision of the Master (Murphy) in Chancery, whether these legacies are chargeable upon and payable out of the testator's real property.

The Committee take this opportunity again to impress on all the friends of this Society the important fact, that its resources are mainly derived from the annual contributions of members.

All the BRANCH SOCIETIES continue in more or less active operation, except that of Galway city, which your Committee regret to say has ceased to exist. Our most distant auxiliary—that namely, of Bombay—is in a most prosperous condition. A short time ago Dr. Lord remitted £60 from this branch, which sum comes in to the present distribution. More recently Dr. Joynt, who has been acting as honorary secretary for the branch during the

absence of Dr. Lord, has forwarded a bill for £50 more; but as this is not yet payable, it cannot appear in the accounts of the year now ending. Your Committee feel it a duty and a pleasure to express their appreciation of the zealous and successful services which Drs. Lord and Joynt have rendered to the cause of our Society.

It is hoped that ere long a branch will be formed for the large and influential county of Westmeath. Dr. Williams of Killucan has evinced a warm interest in the matter, and expressed his willingness to do what he could in gaining friends and supporters for the Society in this quarter.

As regards the FUNDS of the Society, your Committee are most happy to be able to announce that the receipts for the past year show a small increase over those for the year preceding. This increase arises partly from interest on the donations of last year, but chiefly—and this is the encouraging feature—from subscriptions. To enter into particulars or say more on this important subject would only be to anticipate the report of Dr. Duke, the honorary Treasurer.

The total number of APPLICATIONS for relief on the present occasion is seventy, which is about the same as that for each of the last few years. Nine of the above are new applications.

It is worthy of being mentioned that of the recipients of the present distribution seven are medical men, all of whom had once occupied respectable positions, but have been reduced through age, sickness, and other unavoidable circumstances to such extreme destitution as to receive with gratitude the awards—varying from £25 downwards—made to them by your Society. Of the other applicants fifty-four claim relief as the widows, and eight as the children, of medical men.

Two medical men who for some years had been objects of this Society's beneficence, have been removed by death. One of these had been nine years, and the other seven years on the fund, and they had respectively got from it, £69, and £140.

The tabular statement of applications made this year to the Society, with the sums awarded, is now submitted.

The following extracts from the reports, of Local Honorary Secretaries are selected with a view to show the progress and working of the Society in the respective branches to which they relate:—

From ARMAGH, Dr. LYNN writes:—"This year our Subscription List will be rather less, as two of our contributors, residing in the county Tyrone, have intimated their intention of joining the branch in that county, to which we cannot object, especially as the charity will lose nothing, but rather gain, as Dr. Neville promises to double his subscription. By direction of our Annual Meeting, I have again sent a strong appeal, accompanied by the last report of the Parent Society, to all the non-subscribing medical practitioners in this county, twenty-four in number, and hope we shall have some response."

The following communication from Dr. SHARKEY, Honorary Secretary of the BALLINASLOE BRANCH, cannot fail to excite much interest:—"In reply to your circular of the 19th inst., I have to state that I believe the subscriptions from this Branch of the Royal Medical Benevolent Society will be about the same as those of last year; but I have to record an incident in connexion with its working which is of very painful interest. Your Society has for some years allowed a reduced medical gentleman in this neighbourhood an annual sum of £10. He has lately died, and under most distressing circumstances. He had been medical attendant of a dispensary in this neighbourhood under the old system, had become decrepit, and was destitute of all resources, your Society stepped in, thus keeping him from actual want. Happily for him, too, an aged Christian patriarch, the Rev. Robert F. Collis, was the rector of the parish in which he had practised. He and his amiable family kindly looked after him, and advantageously laid out his little stipend, affording him also hospitable entertainment at the rectory, where he was a regular Sunday guest. Within the last

few months preceding his death his infirmities rapidly increased; he became almost blind from cataract, for which he underwent operation, but without relief. At last fatal illness seized him."

The condition and prospects of the BELFAST BRANCH are thus reported by Dr. STEWART:—"The operations of this branch during the past year have been pretty similar to those immediately preceding it, the amount of contributions in subscriptions and donations being much alike.

"It is still a matter of just reproach that so few, comparatively, of the profession, embraced in this branch, feel it a duty incumbent upon them to afford the smallest amount of pecuniary aid in furtherance of the truly disinterested objects for which the Society was originally founded. But this very disinterestedness, it cannot but be confessed—however humiliating to us as a body considered to be a paragon of all that is liberal and humane—operates against larger numbers being enrolled as subscribers. The question is so often asked, 'What am I to gain by becoming a member of the Society? Those who do not subscribe a farthing are just as eligible for relief as those who have opened their purses in the freest and most generous manner. Why should I, therefore, subtract anything from my already limited means in support of a Society upon which I or my representatives have no claim as a right?' And so it is that not a few thus satisfy themselves in withholding their aid and countenance, forgetful altogether of what is declared upon the highest authority, that 'it is more blessed to give than to receive.' It has with great regret and concern to be stated that since last year two regular subscribers of this branch have been removed by death—Professor J. C. Ferguson, M.B., Queen's College, Belfast, and Dr. Samuel Hunter, M.D.—both highly accomplished and most worthy members of the profession. The permanent president, Dr. T. H. Purdon, continues to be a bright example to his brethren by his more than munificent support, and which has been always so freely afforded. He and Dr. Browne, the Local Treasurer, have been requested to be present, if possible, at the ensuing annual meeting in Dublin to represent this branch, and express its continued satisfaction with the Parent Committee's proceedings generally."

Of the CLARE BRANCH, Dr. MOLONY writes:—"In sending the enclosed cheque, with a list of the subscribers to the Clare Branch of the Royal Medical Benevolent Fund Society, I feel much pleasure in pointing out that there is a slight increase beyond the amount subscribed last year, and a very considerable increase in the number of professional men who show an interest in the well-being of the Society by subscribing to its funds. There is one instance to which I shall briefly advert. On the list of subscribers you will see the name of the late Dr. H. O'Flanagan. I wrote to him, on seeing that he had been appointed to a dispensary in the west of the county, bringing under his notice the claims of the Benevolent Fund, and in some time after I received from him a kind letter, saying how happy he felt at being placed in a position to enable him to subscribe to a Society of whose usefulness he had heard so much. I replied, warmly thanking him on behalf of the Society, and in a few short weeks I heard that he had fallen a victim to that scourge of our profession—typhus fever."

From CORK we have the following:—"The Local Committee have to report since the last annual meeting of the subscribers to the Cork Branch of the Medical Fund Society, it has lost through death the valuable services of their late esteemed Secretary and Treasurer, Dr. Corbett. A few days prior to his decease a meeting was held for the purpose of receiving his resignation, in consequence of his declining health, and appointing his successor, when the following resolution was passed:—

"That we have received with sincere grief the intimation from our valued Secretary and Treasurer, Dr. Corbett, of the necessity of his resignation, and deeply do we

deplore the cause which deprives us of a faithful colleague and this institution of a true friend and benefactor. We beg, for ourselves and the Society, to tender him our grateful acknowledgments for the inestimable services which he has rendered to the Medical Benevolent Fund Society by the exercise of an interest, a zeal, and an efficiency seldom equalled.' Dr. Gregg was appointed Local Secretary and Treasurer."

Dr. HAMERTON, Honorary Secretary of the DROGHEDA, MEATH, and LOUTH BRANCH, writes to the following effect:—"We will be able to remit subscriptions equal, if not greater, than last year, a fact which we attribute to an arrangement entered into by our branch of the Society—namely, that ten shillings annually was to be the amount of subscription from each original member of the Meath, Louth, and Drogheda Branch. This year we have circulated a statement put forward by the Central Committee, dated September, 1864, in which five shillings subscription is solicited, so as to render the Society more useful and efficient in affording relief. We have received favourable replies to it. We receive the grateful thanks of those already receiving relief and trusting in a continuance of it. They speak of the assistance it has afforded them."

From KILKENNY, Dr. Z. JOHNSON reports:—"The Medical Benevolent Society does not meet at all the support it ought to do from the members of the profession hereabouts. Appeals to any, beyond those who are in the habit of subscribing, prove utterly useless. There are men holding medical appointments for many years in this district, to whom I have been in the habit of sending circulars annually for years past (sometimes three or four in the year), and from some of whom I have never been able to get even a reply yet.

"I believe an application will be made this June, on behalf of the widow of a medical man to whom I regularly sent two, three, or four circulars for years, and who never sent me a reply, much less a subscription!

"I have only got in two subscriptions yet in reply to a number of circulars, but expect to do better before the 31st, and think it likely my collection will be nearly the same as last year, minus one subscriber, since dead."

Dr. ERSKINE of NEWRY, says:—"I have little to report in relation to the Newry Branch of the Royal Medical Benevolent Society that can be regarded as anything but common place. In addition to circulating last year's report of the Society's proceedings, I have taken all other means in my power to bring the claims of this benevolent institution under the consideration of the non-professional public as well as of those belonging to our profession, and have succeeded in adding two new subscribers to our list.

"It is to be regretted that so much apathy and indifference prevails, not only as regards the public, but also on the part of our professional friends. I think if some of the old supporters of this Society would increase their subscriptions (those of them who have not given donations), it would have a good effect in bringing in new blood. If I were present at the meeting I would move or second a resolution to that effect."

Dr. BRADSHAW, Honorary Secretary of the TIPPERRARY BRANCH, writes:—"I regret very much being obliged to state, that notwithstanding the reports and circulars I distributed widely through the county, I had not that success I anticipated. It is very difficult to enlist the sympathy of many of our professional friends by letter, and those whose duties ought to be foremost in supporting so valuable a charity and advance the interests of the Society, have turned a deaf ear to all entreaties; however, by steady perseverance, we may be able each year to forward some additional contributions."

From WICKLOW, Dr. ANDREW NOLAN writes:—"I regret that the death of Dr. Courtney of Baltinglass, has deprived us of an annual contributor. Our old subscribers hold on, but I am sorry to say I have no new ones to report. I sometimes think that if we asked five shillings from every practitioner we might realize more money."

In conclusion, your Committee confidently entrust the case and claims of this Society to the benevolent consideration of the profession.

They have endeavoured to discharge the trust committed to them to the best of their ability and judgment, ascertaining, so far as it was possible to do, the propriety and necessity for assistance in each instance, and bestowing it as liberally as the case required and the funds would allow. Too often has it happened that the largest grant they could give, consistently with other appeals, fell very far short of the necessities or the merits of the case.

Their increasing experience of the working of the Society only convinces them more and more of its inestimable value, and induces them to commend its cause in the strongest manner to all their professional brethren, reminding them at the same time of the Divine commandment, "That he who loveth God loves his brother also."

## ANNUAL REPORT

OF THE

### MEDICAL ASSOCIATION OF IRELAND.

YOUR Council are happy to be able to report that during the past year the strength and influence of your Association have greatly increased, new members have been added to the Parent Association, new Branch Associations have been formed, or old ones have revived, and a strong feeling of the usefulness and absolute necessity of some such bond of union as our Association affords has become much more universal, and appears to have taken firm hold on the profession. That this feeling may increase is your Council's most earnest desire and hope, for without it no great work can be achieved, and with it there is nothing we have sought for which may not be procured by perseverance in legitimate and respectful agitation.

The first meeting of your Council was held in June, immediately after the last annual meeting of the Association, the approaching dissolution of Parliament and consequent general elections affording good opportunities for bringing Members of the Profession throughout the country into personal intercourse with the candidates for seats in the House, your Council issued circulars calling on our brethren to avail themselves of this great occasion, and urging them to endeavour to procure promises from the members of the new Parliament to support the just claims and moderate demands of the profession. Your Council are happy to say that these suggestions were very generally followed, and would have been universally so had our country brethren given us their entire support in carrying out the organization and working of the Society to its full extent. As it was, however, much good resulted from these exertions, for wherever a branch of the Association existed, or even two or three individual members of it were to be found, interviews were had with the Parliamentary candidates—the grievances of the Medical Officers were explained, and, in many instances, pledges of support to our just claims were voluntarily given. Thus, we have obtained letters from highly influential members of the House. One says, "I have already had many opportunities of speaking with members of the Medical profession on the subject, and have long since been convinced of the justice of the claims referred to in your letter, and have never hesitated to promise my fullest attention and any support I may possess. Colonel — has desired me to express his full concurrence with my opinion."

Another writes, "it is my full intention to support any measure for the superannuation allowance of Poor-law and Dispensary Medical Officers."

"You may rest assured that the various points shall have my full and favourable consideration."

Many others equally strong are in our possession most encouraging expressions of good will, valuable alike as promises of support and as proofs of the working of our Association in making our claims and grievances generally known.

At the next meeting the grievances of the Medical officers of the Army in out stations in India were under consideration, and a memorial on the subject was prepared and forwarded to the Secretary of State for India. At our October meeting the propriety of holding a general meeting of the profession was duly considered, and it was resolved that if the country members of the profession were anxious that it should be held, every assistance should be given to them. A requisition, signed by 350 members, having been forwarded to our President, the meeting was convened for the 28th December, and was held at the Limerick Junction. A number of very important resolutions was adopted, these were afterwards printed and circulated very generally through the country. The success of this meeting, for a most successful one it was, and the unanimity and good feeling which prevailed throughout the discussions at it, were entirely due to the energy and exertions of the members of the Committee of the Cork Protective Society and their untiring Secretary, Dr. Armstrong.

At our next meeting the position of the medical officers of the army and navy, in reference to the carrying out of the Royal Warrant of 1858, was under consideration.

The President of the Association, when forwarding to the Right Hon. the Secretary for War the resolution unanimously adopted at the meeting of the Medical Association and of the medical practitioners of Ireland, held at the Limerick Junction on the 28th December, 1865, addressed to his lordship the subjoined letter, which, with the resolution, was referred to the committee then sitting on Army and Naval Medical officers, and it is gratifying to observe that the views then put forward have been (with one exception) considered by the committee in their valuable report, which, we trust, will be adopted by the military and naval authorities and fully carried out as due to the gallant British soldier and sailor in providing for him competent medical officers.

TO THE RIGHT HONOURABLE THE SECRETARY OF STATE FOR WAR.

"Medical Association,  
"Royal College of Surgeons in Ireland,  
"January 26th, 1866.

"MY LORD,—I have the honour to enclose a copy of a resolution passed unanimously at a numerous meeting of the Medical Association and of the medical profession of Ireland, held at the Limerick Junction, on the 28th December last.

"I trust your lordship will not deem it out of place for me, as President of the Irish Medical Association, to suggest the advantage likely to result from the full restoration of the Warrant of 1858, in again imparting to the medical profession that confidence in the Military Medical Department, so shaken by the manner in which some of the provisions of that Warrant were evaded and subsequently withdrawn. I would further, with much respect, suggest to your lordship, that, from the increased duration of service in a tropical climate, caused by the large force of Queen's regiments now stationed in India, the optional retirement of the medical officer be reduced from twenty-five to twenty years' full-pay service. The duties of medical officers in a tropical climate being severe, and likely to break down health and energy at an early period of life, granting optional retirement to the medical officer on the permanent half-pay of the rank he may have attained, after nine or ten years' service, would be a great inducement for highly-educated physicians and surgeons to enter the service.

"The Committee recently appointed to report on the Military and Naval Medical Department will, I trust, be enabled to define, in a practical and satisfactory manner, the distinction between rank and military command; and propose regulations that will secure to the medical officers of the army the perfect equality, social position, rank, pay, and allowances, likely to induce competent men to enter the service.—I have the honour to be, your lordship's most obedient and very humble servant,

"THOMAS L. MACKESY, M.D.,  
"President Irish Medical Association."

FROM EARL DE GREY TO DR. MACKESY.

"War Office, 31st January, 1866.

"SIR,—I am directed by the Secretary of State for War to acknowledge the receipt of your letter of the 26th inst.,

forwarding a copy of a resolution passed at a meeting of the Irish Medical Association, held at Limerick on the 28th ultimo. In reply, I am to acquaint you that Earl de Grey has caused these papers to be forwarded for the consideration of a committee now sitting on army and navy medical officers.—I have the honour to be, Sir, your obedient servant,

“EDWARD LUGARD.”

“T. Mackesy, Esq., M.D.”

COPY OF RESOLUTION REFERRED TO ABOVE.

Moved by Dr. Chaplin, Surgeon, County Infirmary, Kildare; seconded by Dr. Martin, Portlaw, county of Waterford:—

“Resolved—That while professing our sympathy with the medical officers of the army and navy in the grievances under which they have so long suffered, we venture to express our strong hope that the Royal Commission now sitting will see, that in not disappointing the just expectations of our brethren who are engaged in these branches of the public service, they will best promote the interest of the service and the country.”

(Signed) THOMAS L. MACKESY, Chairman.  
EDWARD J. QUINAN, M.D., } Hon.  
CHARLES ARMSTRONG, M.D., } Secs.

¶ A letter was also addressed embodying the resolution to His Grace the Duke of Somerset, first Lord of the Admiralty, relative to the Naval Medical Officers.

The attention of your Council having been directed to Bills for the Improvement of the Dwellings of the Working Classes which were then before the House of Commons, a petition in favour of that (prepared and introduced by Mr. McCulloch Torrens) was drawn up and entrusted to Mr. Guinness, the member for this city, for presentation.

The Report of the Annual Meeting of the Cork Protective Association was received at your Council's next meeting. The resolutions passed at that meeting are of a most practical and useful character, having reference not only to the working of the Poor-law and Medical Charities Acts, but also to the improvement of the status, position, and character of the Medical Profession. The Derry, Kildare, Tipperary, and other Associations have also held their annual meetings, and have set examples of zeal and energy, which, were they followed by the profession more generally throughout the country, would render their exertions more effectual.

Your Council have been anxiously watching the proceedings of Parliament in the hope that Government would yield to the wishes of the many landed proprietors and gentry composing the Boards of Guardians, who have so frequently and strongly expressed their opinions in reference to the payment of a moiety of the expenses incurred under the Poor-law and Medical Charities Acts out of the Consolidated Fund, but hitherto no notice has been given of any such intention. In fact, no legislation in reference to medical affairs has been as yet proposed this session. The Bill for the amendment of the Medical Act has been spoken of as in preparation, but it has not as yet been printed. A resolution will be before the meeting in reference to this subject, which is one of such vital importance to the interests of the profession and the public.

TUMOUR RESEMBLING THE FEMALE MAMMA.....Dr. Peter Pineo, late Medical Inspector U.S.A., being present at a recent meeting of the Boston Society for Medical Improvement, related the following case:—In April, 1865, a negro, forty years of age, presented himself for examination as a recruit in Charleston, S.C. On being stripped, his physical condition was found to be perfect, with the exception of a round flattish protuberance on the anterior aspect of the right thigh, at about the juncture of the upper and middle thirds. This protuberance was about four and a half inches in diameter, had a glandular feeling, and an elevation in the middle like a nipple, with a depression at its point, and resembled strongly a female mamma. The negro said it had always been there, and from his account it seemed to have been congenital. The resemblance to a female mamma was so great that the examining surgeon called the attention of Dr. Pineo to it. Dr. P. showed a drawing of the tumour.—*Boston Medical and Surgical Journal.*

## MEDICAL AND SURGICAL HISTORY OF THE LATE AMERICAN WAR.

### SURGICAL OPERATIONS.

So far, 13,397 amputations for gunshot injury have been examined and recorded, and the final results ascertained in 9705 cases. We omit the less important, and only give some of the most striking deductions. The returns corroborate the conclusions of Dupuytren, Malgaigne, and Legonset, who combat the disfavour into which this operation has fallen. It was done unfrequently during the late war, but 19 cases recorded, in all of which the ultimate results have been ascertained; all terminated favourably. “The success,” says Surgeon Otis, “of Talleron and other French surgeons with this operation in the Crimea, is well known. Whenever, then, it is impracticable to amputate the forearm, disarticulation at the elbow should be preferred to amputation of the arm. The oval method answers the purpose best in this locality.”

Of 1949 amputations of the arm, of which the results are ascertained, 1535 recovered.

### AMPUTATIONS AT THE SHOULDER-JOINT.

The number of cases of amputation of the shoulder-joint reported is less than the number of cases of excision of the head of the humerus, which latter operation was probably adopted in nearly all the cases in which it was admissible. Of the 237 terminated cases, 93 died, a ratio of mortality of 39.2—6.7 per cent. greater than in excisions.

### AMPUTATIONS OF THE LEG.

Results ascertained in 2348 cases. Mortality 26.02, probably to be augmented by further examination of the returns.

Amputation of the knee-joint has been frequently performed. The returns to October, 1864, give 132 cases, of which 52 recovered and 64 died. In 6 cases, amputation of the thigh was subsequently performed, with 3 recoveries and 3 deaths. Of 49 cases of primary amputation at the knee-joint, 31 recovered and 16 died, while 2 underwent re-amputation, of whom 1 recovered and 1, a scrofulous subject, died. This gives a percentage of mortality in primary operations of the knee-joint of 34.9. The mortality in primary amputation of the lower third of the thigh is much larger than this, and Hudson and other manufacturers declare that the stumps from the operation at the knee-joint give a far better base of support than can be gained in thigh stumps.

### AMPUTATIONS OF THE THIGH.

In 1597 terminated cases, 568 recovered and 1029 died, or 64.43 per cent., which is within a fraction of the mortality after amputations of the thigh in the English army during the latter part of the Crimean war. In the French army in the Crimea, the whole number of amputations of the thigh for gunshot injuries was 1666, of which 1531, or 91.89 per cent., terminated fatally.

Of these 1597 amputations, the date of operation is ascertained with precision in 1061. Of these, 423 were primary, and 638 intermediate or secondary. The ratio of mortality was 54.13 in the former, and 74.76 in the latter.

### AMPUTATIONS AT THE HIP-JOINT.

Of 21 cases reported, 3 recovered. The rest died, respectively, in twenty minutes, before removal to the ward, a few hours, less than an hour, an hour, less than two hours, ten hours, less than one day, one day, one day, one day, two days, four days, five days, eight days, nine days, nineteen days.

One of the most remarkable cases of successful hip-joint amputation on record is Dr. Shippen's case. Private James E. Kelly, Co. B, 56th Pa. Vols., 28 years of age, wounded April 29, 1863, below Fredericksburg. A conoidal musket-ball, fired at a distance of about 300 yards, shattered his left femur. On consultation, ex-articulation of the femur was decided upon and performed by the single flap method, with little loss of blood. The patient

progressed favourably in tent-hospital. By May 28th all ligatures had been removed. June 15th, the patient was captured by the enemy and removed to Libby Prison. Up to this date there had been no bad symptoms. July 14th, he was exchanged and sent to U.S.A. General Hospital at Annapolis, much exhausted by profuse diarrhœa. Internal portion of the wound had united, but external portion was gangrenous. This yielded on application of chlorinated soda lotion. Dec. 23rd, wound had entirely healed, and the patient was discharged, January 12, 1865, he reports himself as in excellent health.

Another successful secondary case is given—Dr. Packard's—the details of which we have recently given in our periscopic department. Another successful secondary case is not included in the tabular statement, as it resulted from disease of the femur in consequence of amputation for injury by a bayonet wound of the knee-joint. The operation was performed by Surgeon Alexander B. Mott.

The total number of hip-joint amputations for gunshot injury, including primary, intermediate, and secondary cases, recorded up to the late war is 82, of which 74 died and 8 recovered, or nearly 10 per cent., while the recoveries in the 21 cases of this war are 14·3 per cent. Since the report was put in print, two additional secondary cases have been reported. In one case the patient died four months after the operation of pulmonary tuberculosis; in the other case the patient was in a satisfactory condition thirteen months after the operation. The experience of M. Jules Roux in the Italian war seems to prove conclusively that secondary amputations at the hip-joint are less dangerous than primary ones, and early amputations at the hip-joint seems admissible in military surgery only in three conditions: when nearly the entire thigh is carried away by a large projectile; when the totality of the femur is destroyed by osteomyelitis, and possibly when, with comminution of the upper extremity of the femur, the femoral vessels are wounded. The anterior single flap procedure has of late been generally preferred.

#### EXCISIONS.

Among the *excisions* there are 315 of the elbow, the results being ascertained in 286 cases. In 16 cases, amputation of the arm became necessary; 62 cases terminated fatally, or 21·67 per cent., which is a fraction greater than the mortality from amputations of the arm. The result will probably be modified favourably, when the statistics are completed.

*Shoulder-joint.*—A total of 575 cases, 252 primary, 323 secondary. The percentage of mortality is 23·3 in primary cases, 38·50 in secondary cases, or a mean ratio of 32·48. The ratio in amputations at the shoulder-joint is 39·24, a percentage of 6·76 in favour of excision. Of 36 cases of gunshot fracture of the head of the humerus, selected as favourable cases for the expectant plan, and treated without excision or amputation, 16 died, or 44·4 per cent., a ratio in favour of excision of 11·96 per cent. The observation of Esmarch, that resection of the left shoulder gives less favourable results than of the right, is not borne out in the statistics of the late war.

*Ankle-joint.*—Formal incisions, it appears from the records, are rarely successful, but the judicious use of the gouge and bone forceps is admissible in gun-shot wounds of the ankle-joints.

*Knee-joint.*—Prior to the late war, there were but seven recorded examples of excision of the knee for gunshot injury, of which two were successful. During the late war, complete excision of the joint was performed eleven times, two recovered.

*Head of the Femur.*—Prior to the late war, the number of recorded cases of excision of the head of the femur for gunshot injury was twelve, with one success. The number of tabulated cases in Surgeon Otis's report is thirty-two (32), with four (4) successes.

Regarding excisions in the continuity of the bones of the extremities, the evidence on the whole, as far as collected, is unfavourable.

#### LIGATIONS.

The following exhibits the number of cases of ligation of the larger arteries, from the beginning of the war to March, 1864:—

|                            | Recovered. | Died. | Total. |
|----------------------------|------------|-------|--------|
| Common Carotid . . . . .   | 12         | 37    | 49     |
| External Carotid . . . . . | —          | 2     | 2      |
| Subclavian . . . . .       | 7          | 28    | 35     |
| Axillary . . . . .         | 3          | 21    | 24     |
| Brachial . . . . .         | 53         | 11    | 64     |
| Radial . . . . .           | 12         | 2     | 14     |
| Ulnar . . . . .            | 9          | 2     | 11     |
| Common Iliac . . . . .     | —          | 2     | 2      |
| Internal Iliac . . . . .   | —          | 3     | 3      |
| External Iliac . . . . .   | 2          | 14    | 16     |
| Femoral . . . . .          | 25         | 83    | 108    |
| Profunda . . . . .         | 1          | 6     | 7      |
| Popliteal . . . . .        | 4          | 12    | 16     |
| Anterior Tibial . . . . .  | 11         | 5     | 16     |
| Posterior Tibial . . . . . | 13         | 6     | 19     |
| Peroneal . . . . .         | —          | 2     | 2      |
| All others . . . . .       | 11         | 4     | 2      |

In all of the 35 cases of ligation of the subclavian, the vessel was secured outside of the scaleni. In 13 cases it was performed for secondary hæmorrhage after amputation of the shoulder-joint, with 4 recoveries. In two cases it was done for primary, and in 15 for secondary bleeding after gunshot wounds, with injury of the axillary artery, with two recoveries. In 2 cases it was performed for axillary aneurism. In two cases, with 1 recovery, it was required by secondary bleeding after excisions of the humerus, and in one case by a secondary hæmorrhage after gunshot wound, with injury to the subclavian.

Acupressure, as recommended by Professor Simpson, was adopted in a few cases, with favourable results.

#### ANÆSTHETICS.

Regarding the employment of anæsthetics, the reports of 23,260 surgical operations performed on the field or in general hospitals, have been consulted. Chloroform was used in 60 per cent. of these operations, ether in 30 per cent., and a mixture of both in 10 per cent. In the field operations, chloroform was almost exclusively used. The returns indicate that it was administered in not less than 80,000 cases. In 7 instances fatal results have been ascribed with apparent fairness to its use.

The report of Dr. Otis concludes with a brief sketch of the organisation of the medical staff in the field, the means of transportation of the wounded, various styles of ambulances, dressings, and equipments.

Interesting and important as are the *surgical statistics* given in the report of Surgeon Otis, and astonishing as are the large figures from which, when the history shall be completed, we will be enabled to draw much more accurate deductions than from any previous collection of statistics, the preliminary report of Surgeon Woodward on the materials available for the *medical history* of the war opens a field yet more extensive and numerically gigantic.

"The matter collected," says Dr. Woodward, "is partly statistical, partly pathological. The first category embraces the medical statistics of the several armies and general hospitals. The second consists of a number of memoirs and reports by medical officers on the causes, symptoms, and treatment of the more important camp diseases, of numerous histories of cases and autopsies, of the fine series of medical and microscopical specimens in the Army Medical Museum, and the results of the pathological studies conducted under my direction on the basis of these collections."

The *medical branch* of the duties of an army surgeon, although popularly considered secondary, and placed in the background by the more imposing spectacle of flourished knives, really forms the essential groundwork upon which the efficiency of an army depends, as far as the efficiency of troops is influenced by their sanitary condition. This need not be told to any medical officer who has been in the army.—*Philadelphia Medical and Surgical Reporter.*

## MANAGEMENT OF THE CORK WORKHOUSE HOSPITALS.

(From the Cork Examiner.)

THE Board of Guardians has recently come to a decision in reference to the management of the workhouse hospitals which bears evidence of haste and want of due consideration, and it may not be out of place to offer a few remarks here in the hope of preventing a serious error from being adhered to. A recommendation has been made by the house committee that the medical officers of the workhouse should not only attend the present hospitals but also the new fever hospital when it shall have been opened; and they prescribe that the physicians shall attend at least three hours a day, of which half an hour is to be at night. The board has sanctioned and adopted this report. Not very unnaturally the board usually adopts the recommendations made to it by committees who have given special attention to the details of particular subjects; and probably in accordance with this practice there was but very little question as to the adoption of a regulation the effect of which may be very unfortunate. As a matter of rule the board is quite right in confiding a good deal in the decisions of its committees respecting details. These committees are composed of gentlemen who are experienced, careful, and trustworthy. But when the matter involved is one of principle, then the board cannot divest itself of the responsibility, and ought not suffer itself to be led by the opinions of a few, no matter how useful in general those members may be. Now those regulations to which we have referred do just involve a very important principle, and the board, if it persist in confirming them, must be prepared to sanction a practice towards paupers which the members would not tolerate towards themselves or their families.

It will perhaps startle some of those who fancy they are working in the interest of the poor when we put their suggestions in this light, but the new rules propose to substitute quantity for quality, and to deprive the inmates of the services of able and experienced physicians. When people travel hundreds of miles to consult Dr. Corrigan, or Dr. Stokes, or Dr. Fergusson, or some of the other great luminaries of the profession, they often find themselves dispatched after a few minutes of keen and practised examination. They do not grumble because they are so peremptorily dismissed. They do not refuse the fee because it has taken so short a time in earning. They know very well that without travelling at all they could get a man who would for as little money be content to poke their ribs, or tap their chest, or punch them in the pit of the stomach for an hour, and yet that fact does not induce them to think all the expense they have been put to ill laid out. Why is this? Because they know that the distinguished surgeon or physician has the rapid insight given by skill and vast experience, and they are satisfied that, though he will not waste time, he will not form his judgment until he has seen and known enough to justify him in its pronouncement. In more ordinary cases it is the physician not the patient who says how often he shall be in attendance. Just as in private practice, so in the management of a public hospital, if the medical officers are fit to be entrusted at all with the patients, they are the best judges of the amount of time they are to bestow and the number of visits they are to give to each particular case. If they are able men they will see as much in half an hour as the inexperienced eye in one hour, or two or three. If they are conscientious men, they will remain as long as their services are required; if they are not, no fixing of time will make them care for the welfare of the patient. Supposing a man really takes no interest in his duties, what does it avail to compel him to spend three hours in the hospital? If he be forced into that course, what is there to prevent his availing himself of the time to read his newspaper? Let this idea be carried into practice, and the next regulation may be that there shall be a minimum of prescriptions, below which the physician shall not go. A good carpenter is said to be known by the quantity of his chips—possibly the doctor's merit may be estimated by the extent of the doses he orders, and his favour with the board augmented in proportion as he deals out largely calomel or castor-oil. What can possibly be more absurd than to place within precise limits that which must vary with every day? There are sick periods and healthy periods, and is the physician to give precisely the same time and attention to both? If an epidemic were raging the public would look strangely upon the doctor who should produce his watch

while a patient was struggling in need of help, and say "my time is out, I must go." This would be bad conduct indeed. Yet is it not the very complement of the regulation which seeks to compel a man to be in attendance when he feels that he is not wanted? If he is to be put through a perfunctory performance of his duty and allowed no discretion as to the time he will give, would it be a very unnatural result if he kept the guardians to the strict letter of their rule, and refused to exceed it when longer services were needed?

There might be some apparent justification for the curious decision of the board if there was any evidence or even any suspicion of neglect on the part of the present medical officers. But it so happens that so far from this being the case the workhouse hospital is managed with rare skill and efficiency. Nay, thanks to the humanity of the physicians and of the system which they have succeeded in enforcing, the old unpopularity which used to attach to the workhouse hospital, which used to make people rot and die in their houses rather than enter it, has altogether disappeared, and there is a readiness to avail of it now which has contributed materially to the preservation of a good sanitary condition of the city. Indeed those medical men whom it is now sought to tie up by rules to do justice to the paupers never had any serious accusation brought against them but one, and that was of *excessive kindness*. They were charged with giving too largely of food and stimulants. Their answer was simple but triumphant. They procured returns from the different workhouses of the country, and these returns shewed that, notwithstanding its eminently disadvantageous situation, the death-rate in it was the smallest in Ireland. Surely the medical men who can only be accused of kindness, and who vindicate that kindness by success, may be trusted to decide for themselves how long or how short should be the duration of their visits.

It appears not to be enough thus to set the medical men running within a certain groove of time, but it is sought to saddle them with new duties. In addition to the infirmary they are to be assigned also the task of attending the fever hospital. This suggestion to provide for the medical care of the fever hospital out of the residuum of time and attention the doctors can give after they have done with the infirmary appears to us to ignore altogether the importance of the former establishment. The treatment of fever is just that branch of a medical man's business which requires the most care and watchfulness. In the existing fever hospital it is thought worth while to employ three physicians; in the workhouse hospital it is hoped to get satisfactory care from two physicians who have just done attending to some hundreds of patients in the adjoining building. Let us remind those gentlemen that a doctor is not a machine—that the brain can become as weary as the legs, and as incapable of sustaining an undue strain. And it is rather dangerous to play with the lives of patients by compelling the medical men, in whose hands their fate often lies, to come to their cases with worn-out and overtasked energies.

What we have written will doubtless at a hasty glance appear to be in the interest of the doctors. We respect the profession, and would willingly do ought to advance it; yet it is not for the sake of the individuals or the profession we write thus, but for the sake of the poor. We feel that the tendency of such courses as we have been referring to is to deprive the poor of the benefit of the highest skill and the widest experience, and to throw them over upon those whose necessities or inexperience will induce them to submit to what they would not bear if they were independent. Doubtless the house committee and the guardians mean well, but they are acting very injudiciously. They are combining with a very mistaken economy a system of arbitrary interference calculated to drive men from their service. There are no doubt many things upon which it may be wise to be sparing of expense, and to be careful in the enforcement of rules. But when lives hang in the balance men do not use to chaffer about a medical fee, nor are the regulations to maintain steady habits amongst ward masters fairly applicable to physicians. Remembering the immense importance of the functions of the physician in the workhouse, we should think it the truest economy as well as the soundest humanity to make the position one calculated to attract the highest intelligence of which the medical community could boast—not a place to be cut the moment a man can live without it.

## Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board on May 30th:—

Anderson, David Hawley Burn, Edinburgh; diploma of membership dated April 24, 1866.  
 Bolton, Reuben, M.D. & M.C. Queen's University of Ireland, 1865. Bangor, county Down. Not a member.  
 Byles, James Cotton, Albert-terrace, Victoria-park-road; June 24, 1865.  
 Creed, John Mildred, Melbourne, Australia; April 24, 1866.  
 Ferguson, Hugh, Haverstock-hill; April 24, 1866.  
 Gibbes, J. Murray, M.B. & M.C. Aberd., Sidmouth, Devon; Nov. 15, 1865.  
 Johnston, David, Magherafelt, county Derry; May 22, 1866.  
 Riley, Joseph, Barnes; April 27, 1866.  
 Shannon, G., M.D. Queen's University of Ireland, Magherafelt, county Derry; Jan. 26, 1864.  
 Smith, Joseph William, Weaverham, Cheshire; April 27, 1866.  
 Stocks, Frederick, Wakefield; April 25, 1866.  
 Thurston, William French, South-bank, Notting-hill; April 27, 1866.

It is stated that three of the fifteen candidates failed to acquit themselves to the satisfaction of the Board.

**APOTHECARIES' HALL OF LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on May 24:

Aveling, Charles, St. Thomas's Hospital.  
 Hills, Rowland, Conisborough, Doncaster.  
 Phillips, Edward England, Norfolk-crescent, Bath.  
 Williams, John, Fishguard, Pembrokeshire.

The following gentlemen also on the same day passed their first examination:—

Hickman, Thos. Henry, St. Bartholomew's Hospital.  
 Salzmann, Frederick William, Guy's Hospital.  
 Smith, Frederick, Westminster Hospital.

**THE REGISTRAR-GENERAL'S** April return for Scotland shows that there were registered in that month 3329 births, a number which was exceeded in April, 1864.

THERE is such a dearth of physicians and surgeons in the Austrian navy that the Government offers to engage young men who have not yet completed their medical studies.

THE French Senate was to debate this week the question of laying a heavy tax on absinthe, suggested by statements made regarding the injurious results of the immense consumption of that liquor in Paris. These statements are contained in petitions drawn up by Dr. Decaisne and M. Agry.

**COLLEGIATE ELECTION.**—From a notice in the *London Gazette* it appears that the annual election of Fellows into the Council of the Royal College of Surgeons of England is appointed for Thursday, the 5th proximo, when two vacancies will be declared, by Mr. James Luke and Mr. John Hilton going out in rotation, but who are eligible for re-election, and who no doubt will again offer themselves. It should not be forgotten that the names of candidates must be sent in on or before June 10th.

**BRITISH MEDICAL ASSOCIATION.**—At the tenth annual meeting of the East York and North Lincoln Branch, held at the Hull Infirmary on the 23rd of May, the following officers were elected:—President Elect: Mr. H. M. Leppingham. Committee: Dr. Humphry Sandwith, Sir Henry Cooper, M.D., Dr. Owen Daly, Mr. Slight, Mr. R. M. Craven, and Mr. Henry Gibson. Secretary: Mr. J. F. Holden. Treasurer: Mr. Joseph A. Locking.

**EXTIRPATION OF SCAPULA.**—M. Michaux of Louvain has lately presented a memoir to the Academy of Medicine of Paris giving an account of the case of a boy, aged fifteen, from whom he successfully removed the right scapula, for an encephaloid tumour involving that bone and its muscles, in November, 1864. The shoulder-joint was disarticulated and the arm left, the scapula having been turned forwards from the ribs, and the disarticulation being effected with the éraseur. The boy recovered from the operation, but died in the following September of a cancerous tumour of the mediastinum.—*Gaz. Medicale.*

**DEATH FROM A SURFEIT OF MUSSELS.**—A man named George Rutland, who had lived for the last fortnight at the Crown and Thistle public-house, Frederick-street, has met

with his death from a strange cause. On Sunday he gathered a quantity of mussels near Black Rock, which he brought home and had cooked. He ate a considerable number, a quart or more, and in a few minutes became seriously ill, and died before medical assistance could reach him. At the inquest held on Tuesday afternoon, the jury returned a verdict that deceased "Died from apoplexy, brought on by retching after having eaten mussels gathered by himself."—*Brighton Guardian.*

**INFECTED CABS.**—In Committee of supply, on Monday last, Mr. Crawford called attention to the great want of precaution in licensing drivers of cabs and other public vehicles. He also complained of cabs being used to convey fever and other patients to the hospitals. Dr. Brady corroborated the statement regarding the dangerous uses to which cabs were often applied, and said he had the authority of medical men connected with some of our hospitals for saying that many infectious diseases were propagated by this practice. Mr. Hankey said attempts had been made to have vehicles set apart for carrying infected persons to hospitals, but the public would not subscribe. Dr. Brady said the Government ought to take the matter in hand and require each parish to provide conveyances for this exclusive purpose. Mr. Candlish suggested that the Poor-law Board should inable unions throughout the country to provide cabs for persons suffering from such diseases. That course had been followed by the guardians in the borough which he represented; and, while it was inexpensive, he had no doubt it was most protective.

**THE PUBLIC MEDICAL SERVICES.**—From an interesting report of the committee on army and navy medical officers' affairs it appears that the total number of candidates examined for the Army Medical Service since 1856 is 922. Of these 713 were passed and 209 rejected. The total number of candidates examined for the Naval Medical Service since 1856 is 569, of whom only 389 were found qualified. During the past year there were only 17 candidates, of whom seven were rejected. That there is no scarcity of medical men is evidenced from the returns of the Royal Colleges of Surgeons of London, Edinburgh, and Dublin, showing that these institutions respectively passed in the preceding year 402, 147, and 131, making a total of 680, and there is no doubt this number will be increased during the present year, as only on Saturday last no less than 108 gentlemen commenced their primary examinations in anatomy and physiology at the London College of Surgeons, and a like number will offer themselves on Saturday next. That the public medical service is distasteful to the profession is shown in the small number entering, and in the large number of resignations after, as since 1850 up to the present time no less than 137 medical officers have left the Royal Navy, and during the same period 117 have voluntarily left the Army, even after 17 years' service. The average age of army assistant-surgeons on promotion to the rank of full surgeon, for the last 11 years, has been 33 years, and the average length of service 9½ years.

**DEATH OF M. MICHON.**—This eminent surgeon, so universally esteemed in Paris, has just died, after a short illness. By his especial wish no discourses were delivered at the funeral, and the body was conveyed to a village, the birthplace of the deceased. M. Michon had for some time retired from his hospital appointments, and was in much request as an operator among the practitioners of the capital. It was justly remarked that certain eminent surgical names sometimes force medical men to a selection insisted upon by patients; whilst M. Michon was always chosen when the medical attendant was unhampered by public clamour. The deceased was particularly conspicuous for his prudence in practice, and for his most amiable disposition. The church where the funeral took place was too small to contain the assemblage of his friends.

**WANT OF SMALL-POX HOSPITALS.**—On Wednesday, Dr. Hillier, medical officer of health for St. Pancras, reported to the vestry that during the past month there has been only one fatal case of small-pox in the parish, but there were ten cases under the care of the parochial surgeons, and he states the disease is very prevalent in some parts of the metropolis, and the Small-pox Hospital is quite full. One day last week a patient was sent from the neighbourhood of Tottenham-court-road to the Small-pox Hospital, and was sent back because there was no room in the hospital. This is another

illustration of the need of increased hospital accommodation for the London poor. One small-pox hospital with 100 beds for 3,000,000 people, is totally insufficient; besides, the distance of any one hospital from parts of London is much greater than any sick poor ought to travel. Although the existing hospital is only just across the boundary of the parish, yet it is a long journey from the southern parts of the district. What is it, then, from Greenwich, Lewisham, Lambeth, St. George's-in-the-East, and other districts?

THE Royal Medals for the encouragement of Geographical Science and Discovery, intrusted annually for award to the Geographical Society, will this year be given to Dr. T. Thomson, Himalayan traveller and botanist, and to Mr. W. Chandless, who, as a private gentleman, performed the wonderful exploration of the Purús river, in South America, mapping it in detail for a length of 1900 miles. The anniversary meeting takes place on the 28th inst.

INFANTICIDE.—At the meeting of the Harveian Society held on the 17th inst., it was proposed by Mr. Curgenven, and seconded by Dr. Hare, "That a committee be formed, consisting of the following members: Dr. Tyler Smith (the President), Mr. J. Brendon Curgenven and Dr. C. Drysdale, (Hon. Secs.); Dr. Hardwike, Deputy Coroner; Mr. Ernest Hart; Dr. Sanderson, Medical Officer of Health for Paddington; Mr. Benson Baker and Mr. Sedgwick, with whom will be associated Dr. Lankester, the Coroner for Central Middlesex, to draw up a report on infanticide, with the object of suggesting the best means of checking the crime; and to report on the causes of death of young children, the best means for preventing excessive infant mortality, and to suggest some plan for the care and rearing of illegitimate children other than the present workhouse system." Communications on these subjects are solicited by the committee, and should be addressed to Mr. Curgenven, 11, Caven-hill Gardens, W.

CRIMINAL ABORTION.—At Clerkenwell, on May 12th Helen Forester, described as a nurse, and her daughter, Caroline Forester, were placed at the bar before Mr. D'Eyncourt, on remand, on the charge of having caused the death of Mrs. Henry Slowman, aged 35, by means of abortion. Dr. Browne said that since the last examination Mrs. Slowman had died. Before her death she made a statement to him and Dr. Walker, in which she described what had taken place. Evidence having been given that the cause of death was the attempt to procure abortion, Mr. D'Eyncourt committed the elder prisoner, who is about 60 years of age, to take her trial for wilful murder, and the younger prisoner as an accessory after the fact.

INFIRMARY FOR EPILEPSY AND PARALYSIS.—An amateur morning concert will be given at Willis's Rooms on Tuesday, June 12th, for the benefit of the London Infirmary for Epilepsy and Paralysis, Charles-street, Portman-square, under the immediate patronage of the Duchess of Grafton, the Duchess of St. Albans, the Countess of Derby, the Countess of Egmont, and other ladies. The programme is very attractive, and many of the most distinguished London amateurs will be amongst the performers.

#### POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Permit me through the medium of your journal to inform the public vaccinators of England and Wales, that I have received a note from a member of the Select Committee on Vaccination, written in haste, in which it is stated, "We have got through the Bill in Committee, have raised the fees, that is, we raised the minimum, the guardians cannot pay less, may pay more." I need scarcely say this is so far satisfactory. As soon as the Bill has been reprinted I am to have a copy, and shall then be able to lay before your readers further particulars of the changes recommended by the Select Committee to Parliament for adoption.—I am, &c.,

RICHARD GRIFFIN.

12, Royal-terrace, Weymouth.  
June 2, 1866.

## Notices to Correspondents.

The Royal Institution of Great Britain.—The notices have been received.

Dr. J.—The name of the person mentioned does not appear in the Medical Directory.

Nemo.—The examinations are held once a month.

## Medical Diary of the Week.

LONDON—WEDNESDAY, JUNE 6.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Professor Hancock, "On the Anatomy and Surgery of the Foot."

OBSTETRICAL SOCIETY OF LONDON.—7 p.m. Meeting of Council.—8 p.m. Mr. R. Fawcett Battye: "Examination of certain Uterine Affections in their relation to Phthisis Pulmonalis, with Cases;" and other papers.

THURSDAY, JUNE 7.

ROYAL INSTITUTION.—3 p.m. Professor Huxley, "On Ethnology."

FRIDAY, JUNE 8.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Professor Hancock, "On the Anatomy and Surgery of the Foot."

ROYAL INSTITUTION.—8 p.m. Professor Frankland, "On the Source of Muscular Power."

SATURDAY, JUNE 9.

ROYAL INSTITUTION.—3 p.m. Professor Huxley, "On Ethnology."

## Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated by the signature of the sender.

#### BIRTHS.

BOWMAN.—On May 25th, at Sunderland, the wife of Henry O. Bowman, M.D., of a son.  
BURKE.—On May 13th, at Bighi, Malta, the wife of John Page Burke, M.D., Staff-Surgeon, Royal Naval Hospital, of a daughter.  
FORESTER.—On May 25th, at Claremont-square, the wife of H. Forester, M.D., of a son.  
LONGMORE.—On May 20th, at Hamble, near Netley, the wife of Deputy Inspector-General T. Longmore, of a daughter.  
MIDDLETON.—On May 23rd, at Brussels, the wife of J. W. Middleton, M.D., of a daughter.  
MOULD.—On May 24th, at Cheadle, Cheshire, the wife of G. W. Mould, Esq., of a son.  
PHELAN.—On May 19th, at Kilmanny, county Kilkenny, the wife of William Bernard Phelan, M.D., of a daughter.  
PHILLIPS.—On May 22nd, at Manchester, the wife of Charles D. F. Phillips, M.D., of a son.  
POTTER.—On May 24, at Cullompton, Devon, the wife of S. Reginald Potter, M.D., of a son.  
SMITH.—On May 22nd at 9, Finsbury Pavement, the wife of W. Abbotts Smith, M.D., of a daughter.  
SPENDER.—On May 21st, at Bath, the wife of John K. Spender, Esq., of a daughter.

#### MARRIAGES.

EBBAGE, Thomas, Esq., of Leamington, to Amelia, elder daughter of the Rev. C. Jeaffreson, M.A., retired Chaplain H.E.I.C.S., at Edmonton, on May 24.  
HALL, Marriott, Esq., Surgeon, Sheffield, to Sarah, elder daughter of Mark Frith, Esq., of Oak Brook, Sheffield, on May 24.  
HARRIS, William John, Esq., of Worthing, to Florentia Caroline, younger daughter of the Rev. C. Jeaffreson, M.A., retired Chaplain H.E.I.C.S., at Edmonton, on May 24.  
OMEROB, Henry, Esq., of Westbury-on-Trym, to Mary Anne Burk, second daughter of J. J. Evans, Esq., of St. Neots, on May 23.  
WALTER, Walter W., Esq., of Stoke-under-Ham, to Mary Drury Grace, eldest daughter of the Rev. — Greenslade, Incumbent of the same parish, on May 26.  
WATSON, A.M., M.D., of Little Hultonwaite, Sheffield, to Fanny Elizabeth, younger daughter of F. Eaton, Esq., of Ancaster, Grantham, on May 24.

#### DEATHS.

BEATSON. On May 18th, at Castletown, Isle of Man, Mary Jane, wife of W. B. Beatson, M.D., Inspector-General of Hospitals in India.  
BROUGHAM, Stephen, Esq., Surgeon, at Falmouth, aged 72, on May 20.  
CANNON, Aeneas, M.D., at Cheltenham, aged 79, on May 15.  
GILLHAM, William L., M.D., at Hereford, aged 51, on May 21.  
NESBITT, Francis A., Esq., of Wolverhampton, at Norwood, aged 34, on May 27.  
NOYES. On May 19th, at Lee, Kent, Louisa, wife of Henry G. Noyes, M.D.  
SISSONS. On February 21st., at Brisbane, Queensland, Cordelia Matilda, wife of Richard Sissons, Esq., Surgeon, late of Huddersfield.  
TATUM. On May 21st, at 3, George-street, Hanover-square, aged 50, Fanny Maria, wife of T. Tatum, Esq., Surgeon.

## WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING JUNE 2ND, 1866.

By J. H. STEWARD, Strand, and Cornhill, London.

### A COURSE OF LECTURES ON ELECTRO-THERAPEUTICS.

By HARRY LOBB, Esq.

#### NO. I.

##### INTRODUCTORY.

GENTLEMEN,—I appear before you with some diffidence to deliver the second series of lectures ever attempted on this subject. Still, having made up my mind to the effort, I purpose to carry it through to the best of my ability; and I trust I may have your forbearance, should I be at a loss occasionally, as having had but one predecessor in this science as a lecturer—the late Dr. Golding Bird. I have not the advantage of the vast storehouses of learning which the lecturers on the practice of medicine, surgery, chemistry, &c., have; I shall, however, cast myself upon your indulgence, and hope to achieve the end I have in view—namely, the imparting elementary knowledge on electro-therapeutics in a clear manner, and in simple language.

The science of medical electricity has been studied for very many years by isolated observers at home and abroad; almost all who have become connected with electricity have been struck with the idea of its adaptability to the treatment of disease. Franklin, Humboldt, Davy, Aldini, Galvani, and Volta, and others too numerous to mention, have recorded their belief in its virtues as a remedial agent; few, however, have practised its use with any serious intention of persevering. Dr. Wilson Philip and Dr. Golding Bird doubtless entered into its study with vigour, and were only prevented from doing great things by the cold hand of death. They have, however, left their mark, and will be remembered with respect by all who follow in the same road.

A new era has dawned upon our science, the labours of Rehak in Germany, of Duchenne in France, have given the mark of legitimacy to that which was a founding: it has been received to the bosom of Father Æsculapius, and, although the youngest of his offspring, is a strong and lusty child, and likely to do credit to its paternity.

Electro-physiology, upon which electro therapeutics must be based ever to hope to be a success, has of late made vast strides. Following in the path first beaten by Galvani, Matteucci and Du Bois-Reymond have pursued their onward course, and now we find a crowd of experimenters eager in the race; Eckhard, Scoutetten, and the most recent, Shettle, gird their loins for the struggle. May success crown their efforts!

Dr. Radcliffe, as you are doubtless aware, has collected together the various experiments and based upon them a theory of muscular contraction, which, whether received or not eventually, is highly ingenious and worthy of commendation.

With this mass of information collected together, it would be indeed a disgrace to let it lie idle: but no; a school of practical electro-therapeutics is rising from this foundation. The present state of the science of medical Electricity is then most encouraging, and I should recommend all entering the medical profession, to well consider this agent, and not to omit its study; otherwise they will find themselves distanced by their competitors, and

there will a day arrive when to be ignorant of the fundamental laws of electricity will stamp the student as neglectful, and will prevent anything like success in practice.

You must excuse me if I pass over the history of the science of electricity, as you will find all that I could say on this head much better expressed in many works you have access to, and I have too much to tell you which you cannot acquire elsewhere.

Electricity is the *Soul of Matter*—the indestructible energy bound up in all that is tangible to our senses. It may lie quiescent for myriads of ages, but it is still there, and can be always called forth at any moment by certain agencies. This force, which is found in all forms of matter, becomes still more evident in vitalized matter: in the organic kingdom it differs in its external characteristics from its prototype in the inorganic, and I shall have to show you the difference between the two.

#### STATIC ELECTRICITY.

Static electricity is a force manifesting itself through the agency of matter by attractions and repulsions, and these are its most important conditions in the inorganic kingdom; but when we come to study it in vitalized bodies, we find that it undergoes a new series of changes differing in their characteristics from what we have been led to anticipate, by its phenomena in the inorganic kingdom.

I must, however, before passing on to the more important field of dynamic electricity, give you some idea of static electricity; but I shall not detain you long on this subject.

The theory, explaining the various electrical phenomena which is now most in favour, is that of Symmer. He assumes that all matter has associated with it a certain quantity of a subtle imponderable fluid, made up of two separate conditions of the same fluid, so that in combination they neutralize one another; but when, by the action of some force, they become separated, the one is termed positive or vitreous electricity, the other negative or resinous. This is a pure hypothesis, and really means nothing, but affords a simple method of explaining many electrical phenomena.

Now we have the means of detecting the presence of one or other of these electrical "fluids" by an instrument termed an electro-scope; here is one termed *Volta's condensing electro-scope*. You will perceive that there are two pieces of gold-leaf hanging from the lower brass plate, the electricity is in a neutral condition; and the gold leaves are consequently at rest; but we have the power of detecting very small quantities of free electricity with this apparatus. Suppose we wish to detect the presence of free negative electricity in a piece of sealing-wax: we place it after having rubbed it, in contact with the lower or collecting plate.

The upper or condensing-plate is connected with the earth, by touching with the finger, and the plate is electrified positively, in contradistinction to the lower plate, which is electrified negatively by means of the wax; but the leaves do not sensibly diverge, as the opposite electrical fluids attract one another, and thus become located almost exclusively on the two plates. If the upper plate be now removed, and with it the source of the positive electricity the negative electricity freely passes to the leaves; and being both negatively electrified, they repel one another and fly apart. Now, after a time, the leaves fall together again from the negative electricity on the leaves combining with the positive electricity in the air: if the air is very dry, this takes place slowly; if moist, rapidly.

This will give you some idea of static electricity, in reference to its combined or neutral state, and its decomposed or active condition.

The states of attraction and repulsion are the most important features of static electricity; but only secondary to these is the inductive state, which electricity has the power of setting up in other bodies at a distance. Our great Faraday considers this power of inducing an opposite state of electricity in matter in a neutral state by the ac-

tion of an electrified body in its neighbourhood, to take place through the surrounding medium, which must be, to a certain degree, non-conducting: thus, in air, the atom in juxtaposition to the electrified body by the inductive power of that body is polarized, the contrary electrical state is induced in the adjacent portion, and a like state is induced in the further portion of the atom; and in like manner from atom to atom, until the neighbouring body is reached, which is consequently in an opposite electrical condition to the inducing body. Now this induced state can only take place if the bodies are at a certain distance, and the quantity of electricity in the electrified bodies of a certain amount; for upon the bodies being made to approach each other, coming within a certain distance so that the attraction of the two electrical conditions overcomes the resistance of the medium, the electricities fly together, and equilibrium is established; or again, if the quantity of electricity in the electrified body is increased, it will at length overcome the resistance of the medium, and again equilibrium will be re-established by combination.

This leads us naturally to the subject of *tension*, which may be defined as the desire of the accumulated electricity to combine, by overcoming the obstacles offered by the medium.

*Static electricity is chiefly induced by friction; it accumulates on the surface of bodies, and manifests its presence by attractions and repulsions.*

And here I shall dismiss static electricity, for we shall have very little further necessity to touch upon this agent, as I shall be able to prove to you that we have a much more valuable agent in dynamic electricity for the treatment of disease.

(To be continued)

## CLINICAL RECORDS ILLUSTRATIVE OF THE DISEASES OF CHILDREN.

By G. STEVENSON SMITH, L.R.C.S.E.,

FELLOW OF THE OBSTETRICAL SOCIETY, AND FORMERLY RESIDENT  
MEDICAL OFFICER, ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.

### V.

#### ACUTE HYDROCEPHALUS.

THE following cases are intended to illustrate the chief symptoms of Acute Hydrocephalus which is one of the most frequent and most fatal affections of early life. The insidious manner of its approach, the extremely painful nature of its course and termination, as well as the resistance it usually offers to all treatment, cause this disease to be regarded both by parents and practitioners with feelings of anxiety and alarm.

It is one of that class of ailments for which unfortunately medicine can do but little; for although in recent years, mainly through the researches of French pathologists, we have become intimate with the structural changes and appearances which generally accompany an attack of hydrocephalus, we are still ignorant of any remedy on which we can rely as a cure. And consequently the annals of medicine record very few instances indeed of recovery having taken place, after any well-marked symptoms of water on the brain had manifested themselves. It is no uncommon thing for patients labouring under the chronic form of the disease to survive for many years, but in them the senses and the intellect are often impaired; in acute cases, however, a fatal result is almost invariable.

*Case 1.*—E. W., aged 6, had enjoyed tolerably good health up till the month of October, 1865; but about that time she began to fall off, her appetite was poor, and she had frequent headaches. On the 1st day of January, 1866, she was seized with a violent attack of vomiting and

retching, which continued for several days. On the 6th she was so exhausted that she had to go to bed, and there was severe pain in the head and back of the neck. On the 21st she had what the friends described as nervous fits, during which the hands were spasmodically clenched, the eyes rolled wildly, and the teeth were ground together. The bowels had been all along confined, and when first seen by me on January 24th she was in the following condition:—Face pale and dingy, eyes sunken and glassy, the pupil of the right eye widely dilated, left pupil natural, conjunctivæ red and injected. She was greatly emaciated, skin dry, pulse feeble, rapid but regular; breathing was gurgling; tongue coated, small and sharp-pointed, fiery-looking at the tip. Though extremely exhausted she was quite sensible, and answered questions correctly. The belly was sunken but the bladder was distended, and about fourteen ounces of urine were drawn off. It was of specific gravity 1007, faintly acid in its reaction, and free from albumen. As the patient was so feeble, ammonia, strong beef-tea, and wine were ordered. On the morning of the 25th the breathing was slow, pulse fluttering, and irregular. She kept constantly pushing the bedclothes down, clutching at imaginary objects, and grinding the teeth all day, and died without any convulsion at eight o'clock the same evening.

*Section thirty hours after death.*—Rigor mortis feebly marked. Hypostatic congestion considerable. On examining the head some adhesions of the membranes to the brain posteriorly were found. Both ventricles were distended with clear fluid. Around the optic nerves the membranes were roughened, and in the fissure of Sylvius that appearance of the textures which has been described as resembling sago was found to exist.

The brain substance was not at all softened, but of a natural firmness.

In the abdomen the mesenteric glands were enlarged.

The left lung was firmly adherent to the thoracic wall anteriorly, but no trace of tubercle could be found in either of the lungs.

*Remarks.*—In this case the approach of the disease was heralded by symptoms which are extremely common, falling off in general health, retching and vomiting, and pain in the head and neck. The headache is generally confined to one side, and according to my experience, pain or stiffness in the neck is almost a constant symptom in cases of inflammatory affections of the head. The roughening of the membrane about the optic nerves was no doubt caused by the deposit of minute masses of tubercular matter.

*Case 2.*—T. J., aged 6, was first seen by me on the 28th of January, 1866. He had been ill for about a week with feverish symptoms. He was restless, cried aloud every now and again, and complained of pain in the forehead. The pulse was 80 and intermittent. Tongue red at the point; pupils natural. Body emaciated, belly sunken, skin dry and dingy. There were some purpura-like spots on the arms and trunk. The urine was acid, slightly albuminous, and of specific gravity 1033. Under the microscope numerous amorphous masses of urate of ammonia were seen. The iodide of potassium, three grainsevery four hours, was prescribed, and as there was some tenderness on pressure over the stomach, a mustard poultice was applied. Wine, beef-tea, and milk were also ordered to be given frequently.

On the 29th the pulse was 132, and irregular. The breathing was gasping and shallow, eyes sunken, but natural. He complained of pain over the spine in the dorsal region, when pressure was made there. He was quite sensible, but tossed about in bed, and coughed a good deal. As the bowels had not opened an enema was ordered, and blistering fluid was painted on behind both ears.

On the 30th patient still continued conscious, but had some difficulty in speaking. The breathing was laboured, pulse 120-140, and very feeble and irregular; pupils unaffected.

On the day following—viz., the 31st January—the

bowels became very loose, the pulse fell to 96 beats in the minute, and he vomited some black bad-smelling matter. Towards evening his motions were very fetid, and passed involuntarily in bed. At midnight he was seized with violent convulsions, which affected chiefly the left side. During the attacks the pupils, which hitherto had remained unaltered, became dilated, and the arms were pronated forcibly. The pulse at this time could hardly be felt, and patient moaned much. He died on the 1st of February, having retained his consciousness till near the close. No examination of the body could be obtained.

*Remarks.*—In this, as in the preceding case, the patient retained possession of his faculties till the close; but it differs from Case 1, in being accompanied by convulsions. The boy was evidently of a strumous constitution, and had previously suffered from pneumonia.

The iodide of potassium has been greatly extolled of late in the treatment of the head affections of children, but like all other remedies, it is too generally found to be of little service. There is one case, however, recorded in the books of the Edinburgh Children's Hospital, in which, after the manifestation of the usual symptoms of hydrocephalus, including convulsions, recovery took place under frequent and full doses of this drug.

In Case 2 I made a daily observation of the state of the temperature of the body, and found that in the axilla the mercury of the thermometer stood as follows:—

|                                   |                |       |          |          |
|-----------------------------------|----------------|-------|----------|----------|
| January 29th,                     | Morning,       | temp. | 97 2-5th | degrees. |
| "                                 | Evening,       | "     | 98 3-5th | "        |
| "                                 | 30th, Morning, | "     | 98       | "        |
| "                                 | Evening,       | "     | 98 2-5th | "        |
| "                                 | 31st, Morning, | "     | 96 4-5th | "        |
| "                                 | Evening,       | "     | 97 4-5th | "        |
| During convulsions,               |                |       | 99 1-5th | "        |
| Feb. 1st, at the moment of death, |                |       | 99 1-5th | "        |

It will be noticed that during the convulsions there was a rise in the temperature, and just at the moment of dissolution the thermometer stood at the same figure—namely, 99 1-5th degrees.

Had there been any doubt as to the nature of the case, any uncertainty as to whether it was hydrocephalus or typhoid fever, the state of the temperature would have been of invaluable service in aiding us to form a correct opinion.

*Case 3.*—J. M., aged 9, had never been a very healthy boy, and some time ago suffered from an attack of inflammation of the lung. He had been pretty well, however, and running about as usual, till one day in the end of the month of September, 1865, when, after eating a raw turnip, he was seized with a violent headache. Two days afterwards retching and vomiting came on, and continued for five days, when he fell into a state of stupor, and had a violent convulsion. When seen by me he was partially insensible, screamed with pain in the head, tossed restlessly in bed, and had a good deal of gurgling in the throat. The skin was hot, and so was the head, pulse small and quick, tongue red and fissured. There was also an occasional short cough. The iodide of potassium in frequent doses was prescribed, and patient was to have milk and beef-tea. Cold was also applied to the scalp. The following day, October 6th, he seemed to be rather more sensible, but still complained of pain in the forehead and face. A small fly blister was applied to the nape of the neck.

October 7th: Patient worse to-day. Eyes very much congested. At times he lies quietly in a semi-comatose state, and then gets restless again and cries out most piteously. An enema was administered, and the bowels were freely moved. The gurgling in the throat continues, and he seems to lack the power to cough up the mucus.

The urine is free from albumen.

October 8th: Patient died quietly, without any convulsion, this afternoon.

*Sectio-cadaveris twenty hours after death.*—The veins

of the head were quite full of dark clotted blood. The ventricles contained a small quantity of greenish-coloured fluid. The cerebellum was adherent to the membranes at several points. The substance of the brain appeared to be healthy.

An examination of the chest revealed an old pleurisy of the right side, which had resulted in extensive adhesions. The pericardium contained about two drachms of fluid. The mesenteric glands were slightly enlarged; liver large but healthy; spleen very dark and shrivelled.

All these cases were regarded as hopeless by the time they came under my care; but they may be looked upon as good illustrations of hydrocephalus in its acute form. It is worthy of remark that in all of them there was distinct evidence of previous inflammation of the chest; while in two of them the mesenteric glands were found to be enlarged. These facts lead us to infer that the patients were of a weakly constitution, and that in cases I. and III. at least, there was a tubercular diathesis. Paralysis was not observed in any of these cases; but it ought to be remembered that frequently loss of muscular power in the arm or leg is the first recognizable symptom of approaching disease of the head. Cases have come under my notice in which a slight dragging of one leg, or a failure in the prehensile power of the hand, was the precursor of a fatal attack of hydrocephalus, and this symptom occurring in a child who has been previously healthy should always be regarded with suspicion. Squinting is another sign of grave importance in all intracranial affections; but in the three cases recorded above it was not present, although in Case 1 the pupils were unequally dilated.

## PAPERS ON DERMATOLOGY.

### No. III.

### HERPES.

By T. W. BELCHER, M.A., M.D. Dub.,

FELLOW, CENSOR, AND EXAMINER, KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE DUBLIN DISPENSARY FOR SKIN DISEASES; AND EDITOR OF "NELIGAN ON DISEASES OF THE SKIN," 2ND EDITION. 1866.

(Continued from page 392.)

M. L., a female aged 9, residing in the neighbourhood of the Dispensary for Skin Diseases, was brought there to me on the 22nd August, 1865.

On examination I found her to be affected with herpes on the forehead, and, in small patches, on the back of the neck, and between the shoulders. A well-defined patch of herpes *circinatus* was visible on the crown of the head.

She was directed to take a small dose of castor-oil; and some tincture of iodine, made as described in one of my previous papers, was applied to the diseased surface.

On the 25th the preceding treatment was directed to be continued, with the addition of a borax lotion, and this was persevered in until the 29th September, when she was discharged cured, and has not since returned.

This case leads me to make a few practical remarks on the general subject of herpes, and in doing so I shall not enter into the vexed question—whether or not ringworm of the scalp be herpes at all; in other words, whether ringworm be a vesicular or a parasitic disease. That it is the latter is maintained by most foreign and by some able home authorities. M. Cazenave did not agree in this view, nor did Dr. Neligan, whose opinion I follow, as stated on page 127 of my recent edition of his work on "Diseases of the Skin." I understand herpes, then, to mean an eruption of small globular vesicles clustered together, and often regularly grouped, on inflamed patches of the skin, usually of small extent, and distinctly separated. The eruption is preceded by heat, tingling, and some degree of redness and swelling in the parts on which it is about to appear. Sometimes, but rarely, there is antecedent or accompanying fever, and in one form the eruption is markedly contagious.

At first the vesicles are globular and transparent,

from annoyance. Some weeks afterwards she consulted me for some other ailment, and both then and subsequently assured me of the entire disappearance of the needle.

This case deeply impressed me with the practical value of the laryngoscope as a means for assisting the surgeon in the extraction of foreign bodies from the pharynx. The only difficulty in its use was to educate the hand to bring the reflection of the forceps in contact with the reflection of the needle. The first effort naturally was to catch at the reflection of the needle with the real forceps; but with extreme patience and great forbearance on the part of the poor woman, after a few efforts I got the knack of ceasing to look at the forceps, and to push them steadily on until their image came into view in the mirror as they passed down into the pharynx. Without the laryngoscope, it is quite certain the needle could not have been got out short of great, and perhaps fatal, violence. I have, therefore, thought it right to put this case on record as a hint to those who may have to deal with similar accidents.

### CASE OF "BLACK DEATH."

By P. C. LITTLE, M.D., F.R.C.S.I., &c.

On the 27th May I was called in attendance upon P. F., a young man, aged 23, fresh, full-blooded, muscular, and apparently of active habits, in whom alarming symptoms had suddenly appeared. For a day or two previously he had been complaining of lassitude and indigestion, but paid little attention to that condition. This morning, however, he became so uneasy and so oppressed in his respiration that he called for medical assistance. On my visiting him he complained of much difficulty of breathing, severe pain in the left side, thirst, and sickness of stomach. His face wore a dusky hue, which was many shades deeper around the mouth and lips. He had a grinning expression of countenance; an unsteady imploring glance of the eyes, which were blood-shot; a twitching of the muscles of the face; a faltering hurried speech, with slight delirium. The tongue was foul, brown, and dry in the centre. The surface of the head and thorax was unusually hot, and somewhat tumefied; the hands and feet rather cool and clammy. The nails of both extremities had a cyanotic appearance. The action of the heart was labouring, irregular, and rapid, 112; the respirations were diaphragmatic, and 22 per minute. There was clearness on percussion over the whole right lung and the superior half of left lung, but the inferior half of the latter was quite dull. The respiration was bronchial and accompanied with mucous râles; the vesicular murmur was scarcely audible in the right lung, not heard in the left. There was rusty expectoration. The bowels were distended with fæces and flatus; the urine was scanty and cloudy, and on examination it was found to be of specific gravity 1018, containing albumen, but no chloride of sodium.

I ordered turpentine stupes to be constantly applied over the left lung; beef-tea and claret to be freely given, and at bedtime an aperient of calomel and jalap.

28th: He appeared more composed; the breathing was a little easier; he rested pretty well during the night; the bowels had been freely moved; the skin was perspiring profusely; he was expectorating large quantities of red frothy mucus. The pulse was more regular, smaller, and quicker, 120. He complained of pain in both sides, oppression of breathing, and weakness.

I advised the turpentine stupes to be kept over both lungs; turpentine punch to be administered every two hours, and an anodyne at bedtime.

29th: He is much worse, and is inclined to coma; his breathing is more difficult and slower, 18; consciousness is less, delirium has increased; his face has become darker, the cheeks and the hands, as far as the wrists, are more swollen, and of a deep purple colour; the feet are affected in the same manner, but in less degree; the legs and thighs have a large mottled appearance. I recom-

mended the former treatment to be supplemented with the frequent administration of small quantities of brandy, and the application of sinapisms to the calves of the legs and soles of the feet.

30th: Consciousness has gone; pulse very quick; respiration hurried; lividity of face and extremities more intense, and large dark patches, something resembling in size and shape leopard spots, cover his legs and thighs. In a few hours after my visit he was seized with a fit of violent delirium and jumped out of bed, when his muscles were found to be quite rigid. The large blotches had become darker, new ones appeared over the body, and he soon expired, a quantity of red sputa flowing from his mouth after death. No autopsy could be procured; but some hours after his decease the discoloration and blotches were less remarkable, and the swelling had in a great degree subsided.

This case is remarkable in the following respects:—

1. Its sudden invasion.
2. Early implication of the cerebro-spinal and sympathetic systems.
3. Typhoid character from the beginning.
4. Peculiar discoloration of the skin.
5. Profuse perspiration without mitigation of the pulmonary symptoms.
6. Bright red frothy sputa.
7. Rapid action of heart increasing with the disease.
8. Resistance to all stimulants.
9. Death, and some of its consequences.

Throughout this singular case the changes in the condition of the skin were extraordinary. The advent of the disease was marked by a dusky discoloration, its progress by deeper tinting, and by the development on the face, hands, and feet of broad dark patches, which, as the disease advanced, became more intense in colour, and at its termination resembled the bruises of a hammer. Another, and perhaps the most important feature in the case, was the early derangement of the nervous system. From first to last, restlessness, anxiety, and semi-delirium, excitement of the circulatory and respiratory organs, and spasm of the voluntary muscles, were present. The pathology of this disease, which is new amongst us, is not yet determined; but taking the loss of balance between cerebro-spinal and sympathetic systems as the cause, we can account for the cutaneous phenomena—the capillary congestion so strikingly shown in the case before us. Congestion of the capillaries of the lungs, skin, conjunctiva, and kidneys would follow a suspension or overbalancing of the influence of the sympathetic nerves which preside over those vessels; but how to ascertain the causes of this loss of nervous balance we are unable, and it is to be hoped that we shall not discover them in the outbreak of a more widespread and well-known epidemic.

1, Lower Dominick-street, Dublin.

### CÆSAREAN SECTION COMPARATIVELY SUCCESSFUL: THE MOTHER LIVED TILL THE SIXTH DAY: CHILD ALIVE AND IN GOOD HEALTH.

By SAMUEL K. CRAWFORD, M.D., Tandragee.

APRIL 3, 1866, I was called to attend Mrs. D—, æt. 30 years, the mother of five children, her youngest living child being five years old. On examination I found so much contraction of the pelvis that I explained to her husband the impossibility of her being delivered *per vias naturales*. The certainty of death, if not delivered, and the chance of life to both mother and child afforded by the Cæsarean section, I intimated to both Mr. and Mrs. D—, the propriety of calling in an assistant doctor; but they said if I would undertake the operation they were satisfied.

Preliminaries being arranged, I, with my own assistant, opened the abdomen in the line of the fibres of the external oblique muscle of the left side, and having secured some branches of vessels which had been cut, I proceeded to

open the uterus. Enlarging this incision to the size of the external one (five and a half inches), I extracted a living male child by a footling presentation, and having removed the placenta and examined that the incision in the uterus had contracted without including any of the intestines, I proceeded to stitch the external wound, which done, I dressed over with a pledget of lint wet with tepid water and covered with oiled silk, and supported the abdomen by a bandage. I then attended to the baby, which I had intrusted to a female attendant after having separated it. I then gave the mother a dose of opium, which, combined with a little hyd. c. creta, to prevent inflammation, I continued to administer. On the fourth day union by the first intention had taken place in the external incision and the patient going on well, but weak, and the pulse flagging. I supported her with proper food and stimulants; but her strength gradually gave way, and she sank on the evening of the sixth day from exhaustion, not from any inflammation which had ensued as the result of the operation. Eighteen months ago I attended her in labour, and delivered her with instruments with great difficulty, owing to the partly contracted state of the pelvis. She had been suffering from pains which commenced six months after the birth of her last living child, and remained with her for three years, during which time she had to be carried to and from bed. I at this time gave her medicine which cured the mollities ossium, but not till the spine and pelvis had become so lamentably distorted as to call for this operation. The antero-posterior diameter of the pelvis at its widest part being less than an inch and a quarter, and opposite the promontory of the sacrum, not even permitting my two fingers when the index finger was placed on the back of the second to turn round. Having performed craniotomy four times, and knowing what space was necessary for that operation, I found it utterly impossible to extract even the base of the skull, had it been possible to break it down. I am fully convinced that but for her strength having been worn out by the excessive pains she had endured she would have overcome the effects of the operation. This short report was kept back to the present date for want of time to put it in shape for publication.

Tandraee, May 29, 1866.

## Hospital Reports.

RICHMOND, WHITWORTH, AND HARDWICKE  
HOSPITALS.  
DR. LYONS'S CLINIQUE.

### FEBRIS NIGRA.—"BLACK DEATH."

IN further commenting on this singular malady, which has so recently appeared in this city, and with such appallingly fatal results, Dr. Lyons discussed the pathological affinities of the morbid state presented by the patients.

It may be well to summarise the cases observed to the present date in the following table:—

| Case. | Date.     | Age.   | Sex.    | Duration.                | Seen by                                                                 |
|-------|-----------|--------|---------|--------------------------|-------------------------------------------------------------------------|
| 1.    | March 19. | Youth, | æt. 17. | Fatal in about 30 hours. | Dr. Stokes,<br>Dr. Benson,<br>Dr. Croly,                                |
| 2.    | May 9.    | Man,   | æt. 25  | " 22 "                   | Dr. Cahill.                                                             |
| 3.    | May 12.   | Boy,   | æt. 11  | " 11 "                   | Dr. Brodin, Dr.<br>White, Coroner,<br>Dr. Mapother,<br>Med. Off. Health |
| 4.    | May 13.   | Girl,  | æt. 22  | " 19 "                   | Dr. Lyons.                                                              |

Case 1.—The first case was that of a young gentleman, aged 17, who had enjoyed excellent health until a short time previous to the illness which proved so alarmingly and rapidly fatal. A week prior to his death he appears to have suffered from indisposition, with very severe headache and darting pains in the eyeballs, and had to remain in bed all day on Monday, 12th March; but he appears to have partially convalesced from this condition by the afternoon of the next day; so much so, at all events, as to

enable him to get up at half-past three p.m., and to report himself in writing to his parents on the same evening at eight p.m. as "nearly all right." Symptoms of cold, with sore throat and some epistaxis, were noticeable for the next few days. However, this young gentleman appears to have in this interval followed his ordinary avocations and joined in public amusements; and reading the history of this case by the light of those which followed, Dr. Lyons regards the slight illness just referred to as in no way connected with, and in no way influencing, that which ultimately supervened and proved fatal. On the 17th March he visited the theatre, and soon after rising on the following day he felt ill, was seized with severe and prolonged rigors, but remained up for a great part of the day. About midnight some dark purple spots were noticeable here and there on the surface. These rapidly increased in number and size, and by the forenoon of the next day large dark purple patches in great numbers covered the trunk and extremities. The pulse rose to 160, cold clammy sweat covered the surface, and in about thirty-six hours from the date of the supervention of the marked rigors of the preceding day, death supervened. In the last hours of life the dark purple patches on the arms and other parts could be seen to extend visibly under the eye.

Case 2.—The patient, a remarkably fine, robust, and healthy young man, aged 25, married, and of steady habits, had some rigors on the evening of the 8th of May, but got up on the morning of the 9th. He felt somewhat unwell, but it was not deemed necessary to seek medical advice until about 1-30 p.m., when, in the absence of Mr. Cahill, he was seen by a very intelligent assistant from that gentleman's establishment. The patient was quite conscious, but the hands and feet were cold, and pains were complained of in the calves of the legs. The tongue was particularly clean, there was no sickness of the stomach, and the bowels were unaffected; the pulse was 112 and feeble.

Dark purple spots were noticeable on the face, chest, and on the legs about a quarter of an inch in diameter, and the hands were of a livid hue. The patient continued in much the same state until about six p.m., when he expired, having retained consciousness till within half an hour of death. The total duration of this case may be estimated as somewhat under twenty-four hours.

Case 3.—A boy aged 11, reported as in perfect health on the previous evening. Sickened about half past six a.m. on the 12th May. He vomited once, and the bowels were once moved; prostration ensued about midday; numerous dark purple spots made their appearance on various parts of the body, and the patient died about six p.m.

Case 4.—The history of this case has been already fully given. The patient, a female, aged 22, in perfect health on the previous night, complained about eight a.m. on May 12, of slight headache and some sickness of stomach, but was so little affected that up to one and two o'clock p.m. she saw and conversed with friends, and no alarm was felt about her until later in the evening. She was seen in consultation about 9.15 p.m., when she was found to be perfectly conscious, voice full and strong, but there was a total absence of radial pulse, and the heart's action was exceedingly feeble, beating to the stethoscope 130 per minute. There was much sense of distress, aching of the back, pains in the calves of the legs and chilliness of the extremities. The surface was covered with dark purple spots, varying from one-fourth to half an inch, one inch and upwards in diameter. They were observable on the face, chest, back, upper and lower extremities, and on the backs of the hands down to the finger nails. A longing for sleep was repeatedly expressed. Hot jars and stupes were at once employed, and the most powerful medicines and other stimulants were administered in quick succession, and were well borne by the stomach. There was no irritation of the bowels all through, although under the impression that the headache first complained of was due to confined

bowels, a scidlitz powder had been taken early in the day. About one a.m. the patient began to wander, and lose consciousness, and the livid spots and patches spread with great rapidity. At three a.m. the face was one uniform sheet of purple black colour, the trunk thickly covered with large purple patches, and the upper extremities to the tips of the fingers one uniform sheet of dark bluish purple tint, while from the hips down the same shade of colour was observable in one unbroken mass. At about twenty minutes past three a.m. the patient expired without a struggle. The coloration was everywhere persistent after death, as it had been during life.

Technically defined, Dr. Lyons regards the disease as the algid stage of an essential zymotic febrile condition, the further development of which is as yet undetermined.

*Comparison with Yellow Fever.*—In the depression of vital power, the more or less extensive blue-black discoloration of the skin in spots, patches, or extensive sheets of colour, covering in extreme cases large areas of the trunk, face, and extremities, and in the rapidly fatal issue will be noticed a marked similarity to certain of the phenomena of purpura hæmorrhagica, of the algid stage of cholera and of yellow fever, to the states of system produced by the bite of certain venomous reptiles, and the condition of the blood in animals hunted to death. As illustrative of the partial resemblance, but marked contrast presented by certain forms of yellow fever and the condition of black death under consideration, the following extract from Dr. Lyons's report on the yellow fever at Lisbon may be read with advantage. The case was an example of the algid form of the yellow fever:—

"It was that of a young girl, aged 16 (Case 22, female wards, Desterro Hospital). She was admitted on the 10th December at ten p.m., having been ill since the 4th. She was described as having exhibited hysterical symptoms on admission. When seen at the hour of visit (nine a.m.) on the 11th, she was still in a profoundly algid state, though all proper means had been used to establish reaction. She lay cowering and shivering under the bedclothes; she was quite pulseless, the hands and feet were cold, and the hands soiled with blood; the face was of a livid bluish tint; the eyes darkly congested and dull; the alæ of the nose, the lips, and teeth, covered with bloody sordes; the tongue was moist, slimy, and bloody; there was complete absence of yellow coloration of any kind; the surface generally was semi-cyanosed, and everywhere thickly covered with well-marked purpuric spots; dark blood oozed from the nose and gums, and black vomit supervened, and likewise vaginal hæmorrhage. There was suppression of urine. She was still hysterical at the hour of visit, trembling, fearful, and disposed to cry. She retained her faculties of sense, could understand questions, and made efforts to reply, but could not articulate. There was but one end for such a case. She died on the following day. The conjunctiva was slightly yellowish post-mortem." "The above description," continues Dr. Lyons, "will serve to convey a brief preliminary outline of the most remarkable characteristics of the algid form of yellow fever." He further remarks in the report: "It will be observed that there has been as yet no mention made of yellowness of skin or other structures. In fact, this symptom was very often wanting throughout in this class of cases, many of them dying without having ever exhibited a trace of yellowness on any part of the cutaneous surface, or even on the conjunctiva, during life; its absence being remarkable in these and other situations till after death. For such cases the term *yellow fever* was an obvious misnomer throughout their entire course."

In the depression of the circulation and deep livid discoloration present in both will be at once seen a resemblance sufficiently remarkable between the algid form of yellow fever and the Irish "black death." In the clearness of intellect and in the undisturbed state of the faculties will be found another point of resemblance. On the other hand, in the absence of yellow coloration before

or after death in the conjunctivæ or other parts in the cases of "black death," and in the presence of hæmorrhage from various parts of the mucous surface in yellow fever, as well as the striking concomitant of black vomit, must be noted very essential points of difference.

Of some of the cases recently observed in Dublin, Dr. Lyons remarks, that the fatal issue was rapid to a degree not often equalled in the most fatal epidemics on record, and he is disposed to conclude that the occurrence of cases of such unusual character and of such marked fatality points to the possible visitation of some epidemic of great severity and of no ordinary character.

*Comparison with Cholera.*—In contrasting the phenomenon of the malady in question with certain of those presented in cholera, Dr. Lyons is of opinion that even still less pathological affinity can be traced than between yellow fever and black death or febris nigra, which may form no inappropriate designation for the disease.

In the cholera sicca, to which alone, in his opinion, the Irish black death can be compared, there is, it is true, an absence of vomiting and purging, and so far a similarity, but the dry cholera is attended with muscular cramps and abdominal pains, and the discoloration of surface is essentially that of minute venous congestion and not that of cutaneous transudation of blood, and after death muscular rigidity is extreme. In cholera, likewise, the voice is often reduced to a whisper, the eye sunk, the nose pinched, the hands and the fingers shrunken, while with absence of radial pulse, some of the most remarkable of the cases of black death exhibited not alone full possession of the faculties, but perfect voice and distinct articulation.

*Comparison with Typhus.*—On reviewing carefully all the phenomena presented by the cases of black death hitherto observed, Dr. Lyons fails to find any support for the opinion which would regard them as examples of any form of Typhus Fever. The insidiousness of invasion, with the early depression of the circulating system, might be considered to establish a faint resemblance, but in the perfect possession of the faculties and distinctness of speech retained to within a short period of the fatal issue by the patients in some of the most marked cases of the black death will be found characters which point to an essential difference from the typhus state in which stupor is a leading and necessary feature. Hence Dr. Lyons dismisses the idea that the malady in question is to be ranked under any form of typhus, or that it has any true pathological affinity to any phase or stage of that morbid state.

*Comparison with States in which the Blood is Poisoned.*—In the records of medicine will be found certain cases in which a septic influence introduced from without has been attended with marked and rapidly fatal results. A yellowish tint of the skin has been noticed in connexion with the state of the blood produced by the bite of venomous reptiles.

In seeking an explanation of the occurrence of those remarkable cases, Dr. Lyons has had recourse to the records of the meteorological conditions of the atmosphere for the period in question. From the meteorological department in Trinity College, Professor Galbraith states that there was no noticeable atmospheric disturbance on or prior to the 12th of May. To Captain Wilkinson, R.E., Dr. Lyons is indebted for copies of the monthly diagrams of the weather based on the observations made at the Ordnance Survey Office, Phoenix Park. On the 11th and 12th May the barometer sank to 29°-4, with a W. and N.W. wind, and the thermometer maximum and minimum rose respectively to 61° and 44°, a combination which was very closely paralleled on the 28th and 29th April, when the barometer stood at 29° 4½, and the maximum and minimum thermometer at 64° and 50° respectively, but the wind was N.E. It is much to be regretted that ozonometric observations are not made at numerous points within the city, and Dr. Lyons suggests that the Sanitary Serjeants should be instructed to keep such records, and that suitable apparatus should be provided for the purpose in the several city districts.

Dr. Lyons remarks on the importance of the indications furnished by the study of cases of such unusual character and such marked fatality. They clearly indicate, in his opinion, a singular and much depressed condition of the "Epidemic Constitution," to employ the language of Sydenham, and it will be fortunate if they do not prove the forerunners of an epidemic visitation. In recording observations of diseases which may be found to be complicated with purpuric staining of the skin, or hæmorrhagic effusion into other situations which have been of frequent occurrence of late, Dr. Lyons enforces the necessity of not being led away by superficial appearances and fallacious resemblances. Each case should be thoroughly investigated before its affinity to those under consideration is too hastily inferred.

### MATER MISERICORDIÆ HOSPITAL.

#### TWO CASES OF ACUTE PNEUMONIA :

ONE TREATED BY TARTAR EMETIC, THE OTHER BY MODERATE STIMULANTS; RECOVERY, AND RAPID CONVALESCENCE IN BOTH INSTANCES.

(Under the care of Dr. HUGHES.)

Dr. HUGHES holds the opinion, that no peculiar or specific treatment is applicable to all cases of acute pneumonia, but that the local inflammation in each case subsides concurrently with the fever. He exemplifies his views by the two following cases in point, in both of which the local mischief was pretty much the same, but the accompanying fever very different indeed, and requiring very dissimilar treatment.

The medical literature of the present day abounds in recommendations from various authorities, as to the treatment of pneumonia, each succeeding one warning his readers against the mistakes of his predecessor and urging the adoption of his special plan.

Dr. Hughes sees in this difference of opinion an additional proof that if we are desirous of obtaining a sure guide to the successful treatment of pneumonia and other kindred states of the system, we must study the type of the accompanying fever, and adapt our treatment to it, viewing each case by the light of its own peculiar symptoms, instead of vainly endeavouring to make one plan of treatment fit all.

Dr. Hughes thinks that if the remedies applied in the two following cases were similar, there are good grounds for believing that the results would not have been so favourable in both.

*Case 1.*—Anthony Sutton, aged 15, residing at Dundrum, a driver of a laundry cart, and previously in good health, got a severe wetting on the 22nd of April, while driving his cart, and kept his wet clothes on him to ten p.m. the same day.

On the 23rd he had rigors, and on the 24th he was admitted to the Mater Misericordiæ Hospital, under the care of Dr. Hughes.

At the time of his admission he was found to have rigors, and also pleuropneumonia of the base of the right lung.

On the 25th he had scanty and rusty sputa, accompanied with high fever. His tongue was foul, white-furred, and thickly coated. He suffered from pain in the side, and constant harassing hard cough. The respiration was 40; pulse 130; and the patient exhibited entire inability to lie on the affected side.

*Physical Signs.*—Slight dulness from the angle of the scapula downwards, with crepitus.

*Treatment.*—The patient was cupped on the back, then blistered on the side; and, after the bowels had been cleared out with calomel, he took small doses of tartar emetic, just enough to control the fever. His diet at the same time being what the French term *absolut*.

No vomiting, nausea, or other unfavourable symptoms ensued from the use of the tartar emetic.

After four days, and not before, the fever abated; first by cleaning of the tongue; the cough became bronchitic, and the physical signs became correspondingly altered.

A linseed poultice was applied to the side, and he progressed favourably with the aid of farinaceous diet, until the tenth day, when the cough had almost disappeared. At the end of fourteen days the lung was found to be normally sound.

In the preceding case Dr. Hughes did not attach any importance to the cupping.

*Case 2.*—Thomas Reilly, aged 23, residing at Drumcondra, by occupation a labourer, previously in good health, and yet of intemperate habits, as long as he can remember, was admitted into the Mater Misericordiæ Hospital, on the 27th April, 1866, under the care of Dr. Hughes, being then, as he himself expressed it, "screwed."

It appeared that on the 24th of April, he wheeled 50 tons (400 loads) of dung out of a canal boat at Lucan; he became greatly heated and drank two glasses of whisky with three pints of porter.

Next day (25th) he came into town in the canal boat; felt a pain in his right side; was not hungry; but being very thirsty, he took a large draught of cold water from a pump, and not feeling relieved, he drank so much as a pint of whisky during that day.

On the following morning (26th) he got up; drank a pint of porter, then a glass of whisky, after which he went to bed.

On the 27th, as before stated, he was admitted to hospital.

On the 28th Dr. Hughes saw him for the first time, and heard complaints to the effect that the patient throughout the preceding night had moaned in his sleep, and shouted so as to disturb the other inmates of the ward. His face was now of a mahogany colour; he lay on the right side, and moaned with pain; his breathing was very short, and catching; he was covered with a clammy perspiration, the pulse was small, weak, and 80, beyond which number it never rose; the respiration was 30; the tongue was coated with a white *blankety* fur, and was red at the tip.

*Physical Signs.*—Dulness on percussion from the angle of the scapula to the base of the lung; bronchial respiration, and bronchophony over the same space, with crepitus a little higher up. Sputa pneumonia (prune-juice) with troublesome ecugh.

*Treatment.*—For one day this man got calomel and opium, which, however, passed off by the bowels. Further, he took a stimulating mixture of æther, camphor and ammonia; one ounce of wine every two hours; beef-tea *ad libitum*; a blister to the affected side, followed by a large poultice, which was constantly repeated. He was convalescent on the sixth day after admission (1st May), and continued to gain strength from that time forward. The rapid convalescence in both these cases is particularly worthy of note.

## Proceedings of Societies.

### HARVEIAN SOCIETY OF LONDON.

MAY 17TH, 1866.

Dr. TYLER SMITH, President.

#### DEBATE ON INFANTICIDE.

MR. CURGENVEN, in opening the "Debate on Infanticide," desired to direct the attention of gentlemen present to the consideration of the crime as it presented itself to them in its social aspect, rather than to the pathological evidences to be found in the various modes of death. This latter would involve a lengthened discussion on a subject with which they as practitioners were tolerably familiar. The former was a subject worthy their most serious attention, as it was surrounded by many difficulties and presented many debatable points. He would call their attention to the reported increase of infanticide in this metropolis. In one district alone—Central Middlesex—the numbers were

reported to have increased from 84 in 1863 to 114 in 1865. He hoped and believed that some of these cases were the bodies of still-born infants, or of those that had lived but a short time, placed where they had been found by persons in order to save the expense of burial. He believed many bodies of infants were disposed of by being thrown into the river, the canal, or other places, by paupers who were unable to pay 7s. 6d. for burial. Some gentlemen present might possibly suggest means for checking the crime, which, from the reported cases, appeared to be confined principally to the class of domestic servants. His opinion was that, if through an alteration in the bastardy laws, the mother was led to feel that she could rely on the father being compelled to support his offspring, she would in many instances be spared the temptation, which ruin and poverty brought upon her, of destroying the child which prevented her earning her livelihood. It was no use to shut their eyes to the fact that a great many illegitimate children were born of domestic servants; they could all call to mind numerous cases in their practice. No power could prevent their occurrence, but it was the duty of the Legislature to entail on the man some of the consequences of his acts, while it provided for the safety of the woman and her child. How was it at present? Why, the most guilty party escaped, having perhaps promised marriage or paid a trifle for a few weeks, until he could place himself out of the reach of his victim. She, helpless, with an infant in her arms, forsaken by her relatives and former friends, was unable to bear up against her poverty and difficulties, and was tempted to destroy the innocent cause of her sufferings. Again, many children were destroyed during or soon after birth, the woman seeing, in the discovery of her situation, her future ruin, was tempted to conceal her shame by the destruction and secretion of the infant. Did she know that the father would be called upon to support her and her child, and that she would meet with some sympathy from those around her, she probably would not be tempted to commit the greater crime.

He would now direct their attention to a class of cases ten times more numerous than infanticide, but which he considered were but one degree removed from child-murder—he alluded to the numerous deaths of illegitimate children through neglect, he would say *wilful* neglect, on the part of those having the care of them. As medical men they were usually called in a few hours before the child was expected to die, that they might certify that the child died of convulsions, bronchitis, diarrhoea, or marasmus, the most common forms of death of these ill-fed, neglected infants. It was very rare that the mother nursed or reared her illegitimate child; she was forced to get a situation, and work for its maintenance. The child was placed in the care of a woman who, perhaps, had several others, and she received a weekly sum, and undertook to rear the child. Should the remittances cease, which not uncommonly occurred, the child was neglected and did not long survive. They all knew how difficult it was to rear a child by hand with a mother always anxiously watching, and a medical man guiding the selection of its food and ministering to its ailments. How much more difficult, might he ask, was it to rear children by hand by paid or unpaid nurses, ignorant, and in many cases paupers, who had neither interest nor affection for the nursling. Some remedy must be sought for this state of things, and he saw no remedy but a more perfect and compulsory registration of births and deaths. The residence of the mother or nurse of the illegitimate child should be registered, that she might be under the surveillance of the parish authorities or the police for at least twelve months; and no child, mature or otherwise, still-born or not, should be buried without a medical certificate of the cause of death. The two classes of cases he had brought before them, be considered, deserved their earnest attention, and he hoped some suggestions of alterations in the laws would be offered that would be worthy the attention of the Legislature.

Dr. BALLARD said that the mortality of infants was closely connected with the question of infanticide. With regard to infanticide, he feared it was difficult to suggest any remedy for it, as society was now constituted; but with regard to the excessive mortality of infants under the age of twelve months, he entertained very strong opinions as to the causation of a vast amount of it. Thus he thought the paper of the much esteemed lady, Mrs. Baines, who had written on this subject, and addressed a letter this evening to the Society enclosing her paper, contained some statements rather apt to mislead. He had often found that mothers, from a natural desire to suckle their own child, caused its death, on account of their being unfit to act as nurses. He believed that this was one of the great sources of infantile mortality. He had on several occasions urged this view of the matter on the profession, and had attempted to point out how many infantile maladies were caused by fruitless suckling of infants.

Dr. DRYSDALE said the causes of infanticide were not difficult to be understood. In the first place, there was—what medical men were least of all men apt to overlook—the intense appetite of sex, acting, like the force of gravitation, constantly to tempt to a union of the sexes. Then, again, there was the well-known evil of bringing new beings into the world without the means of securing their existence. In the case of the poor, who usually married young and begot large families, many of the children, it was well known, died from the privations they had to undergo from the poverty of their parents. If it was difficult, then, for poor persons to maintain their offspring, even when they had the sanction of society for begetting them, of course it was enormously more difficult for a poor single woman, whose motherhood procured her only ruin and disgrace, to do so? And thus it could readily be seen why domestic servants, rather than any other class of women, such as factory girls, committed infanticide, since with the former character was necessary for existence. Although he thought that possibly Dr. Lankester had a little exaggerated the frequency of infanticide in London, he could quite understand why this phenomenon was on the increase. In the first place, the number of marriages had of late years been decreasing in this country. Thus, the Registrar-General's reports showed that, from 1796 to 1805, there were 1716 marriages in 10,000 women; whilst from 1836 to 1845 there were only 1533 marriages to 10,000 women. Continental statistics told a similar tale. For example, Sir W. Wilde said that in Vienna one out of every two births was illegitimate; in Munich, in 1838, there were 270 more illegitimate than legitimate children born; in Paris, some authors said that one-third of the births were illegitimate. The causes of these remarkable facts were no longer a mystery. Ever since the publication of Malthus's great "Essay on Population," it had been well known to the thoughtful few that there was no hope of successfully coping with such topics as infanticide, unless parents in society were convinced of the great evils they inflicted both on society and on their children by the production of large families. The thoughtless conduct in this respect of the majority in this and other old countries inflicted the evils of low wages upon the great mass of the citizens, and infanticide and other distressing consequences followed. Mr. Stuart Mill had pointed out very frequently, in his splendid work on "Political Economy" (without reading which work, the speaker said, no one was, in his opinion, competent to discuss any question in social science or public hygiene), that the great hope for the future of the labouring classes of both sexes lay in the prospect of their soon being led to perceive that the production of a large family was a grave social offence, not something to be proud of, since it overcrowded the labour market in all trades and professions. The mortality of children in different countries was a good index of the state of society existing in the several states. Thus, in the long-lived country of Norway, where the condition of the peasantry was probably superior to that of any other European state, out of 100 children born 83 attained the age

of 5; in England 74; in Russia 62; and in Italy 61. Comparatively few children were wilfully killed by their parents; but there could be no doubt that the great distress caused by large families caused many mothers to neglect their children in a way which no less certainly caused death. The great dislike felt by many poor mothers to augmenting the numbers of their families was daily seen in hospital and dispensary practice, where mothers came so frequently with infants at the breast at the age of eighteen months. It was said that in Norway many suckled their children three years, in order to avoid another conception. He quite agreed with Mrs. Baines, that bringing up by hand was a most frequent cause of infantile mortality; three-fourths of all such children, it was well known, died shortly. All practical measures for lessening infanticide must be based on a knowledge of the facts he had stated. For example, with regard to foundling hospitals, as hitherto conducted, they were only a legalised state infanticide. Thus, in France the foundling hospitals received, according to M. Legoyt, 30,000 children annually, and the mortality in them was more than 50 per cent., whilst poor mothers only lost 29 per cent. of their children. In Austria, the Government of which country, according to Sir W. Wilde, encouraged illegitimacy and discouraged marriage, because married women were known to have so many more children than single ones, women were, it appeared, received into public lying-in hospitals, without any questions being asked, and their children sent to the Foundling Hospital if they desired it. It might, then, be presumed that infanticide was rare in Vienna; but, then, the mortality in the state foundling hospitals was very great. Again, a proposal had been made by an eminent writer, Dr. Farré, in a recent essay on "The Mortality of Children in different States in Europe," that, as some families were childless, adoption of the children of those who were prolific and poor should be encouraged. Such a suggestion was not, he conceived, practical, since no one but the few would think of such a thing, and besides, it would encourage persons to beget offspring, and then thrust them on others, who were more prudent and self-denying. Summing up the question, he thought that infanticide might be diminished by making the marriage law less severe than it now was, and permitting divorce without any loss of character to either party desiring it. This would doubtless make marriage more common. Again, women should be encouraged and permitted to take up any employment they pleased, by which means their wages would be increased, and they would not be obliged to take to prostitution or infanticide from the force of circumstances. But the most important point was, that the stigma of society should not, as now, be so severe against the maiden-mother, who had one child, whilst it was so lenient to the other woman who entailed, even in the married state, suffering and ignorance upon a numerous and guiltless progeny. Lastly, infanticide should not be punished by death, since this tended now to bring the law into contempt. Lying-in charities should, in the true Christian spirit, be made available for all poor pregnant women, not alone for married women. But, above all, this matter should be openly discussed, not ignored, as hitherto.

Dr. JOHN THOMPSON said he had had much experience of cases of infanticide in his capacity as local magistrate in a country district. He could not agree with Dr. Drysdale that infanticide was in any great degree attributable to poverty, since he had not found this to be the case during a residence of twenty-three years in North Devon. He did not remember more than one case where poverty was the cause. His own idea was that the present law, regarding the maintenance of illegitimate children by their fathers, required much alteration. He did not, however, think that much more money compensation could be exacted from them. "As the law now stood, 2s. 6d. was the sum required to be paid weekly. It was no use asking a large sum in most cases, because the fathers were, in country districts, totally unable to pay more than a small

weekly sum out of their wages. He had, however, often wondered that no one had called attention to the fact that, in the case of a man marrying a woman with an illegitimate child, the whole expense of that child after this devolved on the step-father. He thought some alteration was needed in the law with regard to this point.

Dr. HARDWICKE said he should not like the opportunity to pass without saying a few words, although he could add nothing to the remarks made by the coroner for Central Middlesex (Dr. Lankester) in his third report of inquests for 1865, to which he would refer for full details of circumstances relating to infanticide. If Dr. Lankester had apparently exaggerated the extent of the crime of infanticide in this country, it was not that evidence of it could be found in the verdict of coroners' courts, for they certainly did not take cognizance of half the cases, whilst many escaped observation by being buried as still-born children, there being no registration needed for the burial of this class of infants. An amendment of the hasty law offered one chance of meeting the case of those unfortunate females who are badly protected by the law in the maintenance of their illegitimate children. That change in the law also recommended by the Commission on Capital Punishment, making it an offence punishable by imprisonment, or penal servitude, for a woman who maliciously or wilfully injures her child at or after birth, would bring many cases to justice, which now easily escape conviction under the present state of the law. Unfortunate and needy women, with a prospect of illegitimate offspring, required more protection than our institutions afforded them, and he (Dr. H.) was not inclined to endorse the opinion that foundling hospitals were sources of evil rather than good. Certainly industrial institutions, or houses, if maintained at the expense of the state or parish, would tend to avert much misery and disgrace to young women, and would save rather than increase the expense of crimes that sprung from the present way of dealing with mothers and their illegitimate offspring by the union workhouses.

Mr. BENSON BAKER had had large experience of infanticide and infantile mortality. He lived in a part of town where large nurseries for children existed. It was by no means uncommon to see in one room, three, five, or seven children nursed by one woman. The mortality among such children was very great, and in no one instance in which inquests had been made had he ever seen the father appear. Public opinion was required to put women in their proper position. Industrial homes ought, he thought, to be established, where women might enter after their confinement was over, as it was, ten days after this took place they left their children and entered service.

The PRESIDENT said he had often heard the Coroner Mr. Wakley, speak of infanticide. That gentleman held that the best policy was to stifle the matter and say as little as possible about such cases, and he consequently avoided inquests in cases of suspected infanticide. He (the President) believed the contrary, and thought it was much better, as Dr. Lankester was doing, to bring these questions before the public, and into the light of open discussion. He was sure that a great deal of infanticide escaped unknown. Thus, he had been told, that women were frequently delivered into wash-tubs, the room where they were confined being made to assume the appearance as if washing were going on. There was, he regretted to say, no efficient foundling hospital in London. He did not agree with Dr. Drysdale that, because so many children died in foundling hospitals in France, an equal number would die in this country, if similar institutions were in existence here.

Mr. SEDGWICK, in reply to an observation of the President that nothing had been done during the last hundred years to increase the provisions made for foundlings, remarked that, within the last two years, an institution, entitled "St. Saviour's Hospital and Refuge for Destitute Women and Children," had been established by private charity, with which he had the honour of being professionally associated. Its object was to check the increasing sin of infanticide, by affording a shelter to outcast and

friendless women and children: It contained a nursery, in which children were received from the earliest age; a boys' and a girls' school, in which the children received a plain education, and were trained for service, suitable situations being obtained for them before they leave; and, lastly, a Refuge, distinct from the rest of the house, and fitted up for the reception of outcast females, to which is attached a lying-in ward. Mr. Sedgwick, in conclusion, remarked that Dr. Lankester, as visitor, had cordially approved of the institution, and that Miss Willis Fleming of 35, Bryanston-street, who was its superintendent and chief support, would willingly give any further information on the subject.

Dr. CLEVELAND said there was a remark he wished to make—namely, that it was deplorable with what facilities certificates of death were procurable in some cases. He instanced the case of a girl who was delivered of twins, one of which died, and she obtained a certificate of its death; but on her coming again to demand a certificate for the second, it was refused until an examination was made. She immediately said it was of no consequence, as she knew a doctor at Islington who would give her the certificate without any trouble. He thought the Harveian Society would do well to bring some such matters before the attention of the Legislature.

Mr. CURGENVEN, in reply, said he was glad that some practical suggestions had been offered for checking the crime of infanticide and the excessive mortality obtaining among illegitimate children. The medical profession had always led the van in social and sanitary reforms, and he considered that the Harveian Society, from the labours it had devoted to the social evils, could not perform a higher duty than to act on the debate of this evening, and bring some suggestions, supported by evidence and facts, before the Legislature and Poor-law Board that might lead to alterations in the laws, whereby those evils might, in some degree, be checked. He would propose "that a committee be formed, consisting of the following members:—Dr. Tyler Smith, the President; Mr. Curgenven and Dr. Chas. Drysdale, the Honorary Secretaries; Dr. Hardwicke, the Deputy Coroner; Mr. Ernest Hart; Dr. Sanderson, Medical Officer of Health for Paddington; Mr. Benson Baker and Mr. Sedgwick, with whom should be associated Dr. Lankester, the Coroner for Central Middlesex, to draw up a report on Infanticide, with the object of suggesting the best means for checking the crime, and to report on the causes of death of young children, the best means for preventing excessive infantile mortality, and to suggest some plan for the care and rearing of illegitimate children other than the present workhouse system."

Dr. HARE seconded the motion. He considered that the labours of such a committee as proposed would be attended by many good results.

The proposition was put and unanimously adopted by the meeting.

Communications on this subject were invited to be sent to Mr. Curgenven, 11, Craven Hill Gardens, W.

## MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.

30TH MAY, 1866.

EXTRA MEETING—SESSION, 1865-66.

Dr. HENRY KENNEDY in the Chair.

Dr. MARCUS EUSTACE read a paper entitled  
CASES OF INSANITY OF DIFFICULT DIAGNOSIS TENDING  
TO CRIME.

A number of cases were brought forward that had come under his observation, in which considerable difficulty of diagnosis had occurred in the earlier stages, but after a time, becoming more evident, it was ascertained that a tendency to crime had existed all through. He laid much

stress on the fact that in the slighter forms of insanity the early symptoms are very obscure, and in relation to crime demand our serious consideration. The paper concluded with the following observations:—"We must not forget that, as one mind differs from another, so we find the manifestations of mental disease to vary in the slighter and more obscure forms. As insanity becomes evident, our power of comparison with similar cases is easier, and there is not much difficulty in the diagnosis of confirmed cases.

In dealing with the more obscure, we have to take the most trifling changes from the normal standard into consideration, feeling the weight of responsibility that is attached to our opinion in pronouncing these apparently slight changes in temper or capacity to be the first symptoms of incipient derangement, symptoms which, if not recognized, will ere long clear up the terrible doubt and render it easy to place them under one of the heads of confirmed insanity.

It is therefore desirable to place on record as many of the slighter forms as we can that we may be able, by comparison of history and sequence, to derive assistance in similar cases.

How much crime and misery and impossibility of cure from duration would be avoided by early correct diagnosis!

In judging the question of criminal responsibility, it is essential to take into consideration the form of delusion, and what bearing it has on the crime committed.

I hold that if the unsoundness of any particular faculty can be ascertained, the exercise of that faculty in all its bearings partakes of that unsoundness, and by its nature, if it bears upon other faculties, they will be also unsoundly influenced; but I consider grave doubts arise when a delusion or change of disposition manifests itself in such a way as to make it impossible to trace any connexion between it and the crime committed.

In the cases I have enumerated no sound decision can be arrived at without keeping this in view, and by its just application much of their difficulty is removed.

Homicidal and suicidal insanity are but varieties of the same morbid impulse, and in many cases alternate from one to the other occasionally; one form will maintain the predominance when unexpectedly it will be supplanted by the other, and an unforeseen tragedy be the result. I therefore lay much stress on suicidal impulse, believing it to be a symptom of insanity tending to similar crime, and that it should at all times claim our serious and anxious consideration.

The following gentlemen took part in the discussion:—Drs. Grattan, Duncan, Darby, Gordon, and the Chairman.

Dr. J. A. BYRNE read the history of a case of

### PUERPERAL FETID PULMONARY ABSCESS,

which occurred in private practice. The lady, a healthy primipara, aged 30, was ten hours in labour, the second stage having occupied five hours, and, with the exception of some post-partum hæmorrhage, there was nothing to complicate it.

On the third day she had a slight rigor, followed by pyrexial symptoms and some pain and tenderness in the pubic and iliac regions. This yielded to treatment; the pulse, however, remained quick, 108, and there was insomnia for several days and nights, for which opiates, &c., were employed.

On the sixth day she complained of a stitch in the right side, and had some dyspnoea and cough, but there was no evidence of pulmonary or pleuritic affection. She was ordered a small blister and anodyne expectorants; her pulse still retained its frequent character; she still passed the night without sleep; had no milk; had no care for food, &c.

On the seventh day she was attacked with maniacal symptoms of a most aggravated character, ushered in in the usual manner—viz., by excitement, sleeplessness, and then lost all control over herself; and there was decided

mania for several days. During this period the pain in the side was not complained of, nor was there any cough, dyspnoea, &c., nor any manifestation of metritis or peritoneal inflammation. In fact, the case seemed to be one of decided puerperal mania, and she went on thus for a few days. The symptoms at length yielded to treatment, and she became rational, began to take food and slept.

Simultaneously with the decline of the maniacal symptoms, the pain in the side and cough again became developed, and her pulse retained its quick character. She began to suffer from night perspirations, and complained of a peculiar offensive smell or fœtor coming into the mouth, and so great as to create a repugnance to food, when, on the twenty-sixth day after delivery, after a prolonged fit of coughing, dyspnoea, &c., she expectorated a large bowl of a greenish-coloured purulent fluid, possessing the most intolerable gangrenous fœtor. It was so strong that it seemed to pollute everything in the room, and caused herself the greatest disgust. There was no appearance of blood in it then nor at any subsequent period. The evacuation of this caused great temporary relief, but after some time the symptoms would return, and she then would cough up the same fluid with the same relief, and after some days this would be repeated.

Dr. Stokes saw her in consultation and agreed with the diagnosis. The treatment consisted in removal to the country, tonics, wine, &c. About this time a small abscess containing healthy pus was opened over the upper part of the spine.

She for some time improved, and the cough, expectoration, &c., would diminish, but at length she succumbed and died, three months exactly from the period of her confinement worn out by hectic.

Dr. Byrne remarked upon this pulmonary affection, so rare always, but, as a puerperal consequence, so rare that he was not aware of any case on record, nor had he himself ever seen a similar case whilst assistant in the Rotunda Lying-in Hospital, although he had seen every other form or variety of primary and secondary puerperal affections—nay, even he had seen once that exceedingly rare form—viz., deposit of pus in the anterior chamber of the eye—the most frequent site for puerperal deposits being in some of the articulations. Rokitsansky, however, states that rheumatism is by no means infrequent in the Vienna Lying-in Hospital. The transitory nature of the mania which ushered in the attack, too, was a feature in the case, possessing some interest, it ceasing as soon as the pulmonary mischief developed itself. Since he had detailed this case he had seen at Bray a case under the care of his friend, Dr. Darby, in which the patient, a primipara, manifested decided maniacal symptoms, preceding decided abdominal mischief after her confinement. So suddenly did it set in that the patient was half-way up a chimney before the nurse was aware, and in this case the patient had quick pulse, &c. &c. Authors have dwelt only in a very cursory manner upon this form, as it may be termed, of symptomatic mania. Dr. Byrne also drew attention to the obscure nature of the pulmonary signs both preceding and accompanying the purulent fœtid expectoration. At no period was there any evidence of pleuritic effusion, pulmonary compression, or solidification, or pneumo-thorax, or cavity, in the cases related in Dr. Stokes' celebrated work upon pulmonary diseases and symptoms of cavity here diagnosed; but in this case, although Dr. Stokes and himself examined most carefully on two occasions, was there any sign except slight dulness at the lower part of the right lung posteriorly, and some laterally. However, it was possible that signs of a cavity became subsequently evident, as he did not see the case for five or six weeks preceding her death, as she had been removed to the country. Dr. Stokes lays particular stress upon the fœtor as a sign of this disease, and states that it may always be recognized by it. Dr. Byrne thought that the explanation of the occurrence of the pulmonary attack was this—viz., there was first metro-peritonitis, as evidenced by the pain, tenderness on pressure, and rigors, &c. &c. Phlebitis then

took place, and the site selected for the pus to form was the lung, and during the intermediate stage mania shows itself, subsequently disappearing. The case was remarkable for presenting these three features of interest—viz., 1, a purulent deposit forming in the pulmonary textures; 2, the walls of this abscess being gangrenous; 3, mania, periparturition, preceding the secondary development, and then subsiding.

## SUMMARY OF SCIENCE.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES B. C. TICHBORNE, F.C.S.L., F.R.G.S.L., &c.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

**DISINFECTANTS AND THE CATTLE PLAGUE.**—The last report elicited by the Royal Commission is from the pen of Mr. William Crookes, the well-known editor of the *Chemical News*. In the selection of disinfectants, Mr. Crookes remarks: "It is necessary to strike off at once a whole class of valuable agents which will not meet the requirements of the case." It appears to have been satisfactorily proved that the infectious matter passes off mainly from the lungs of diseased animals, and that the virus attacks healthy ones through the same channels. It is suspended in the air with fogs, vapour, and gaseous products of decomposition, settling on rafters, and in crevices, whence mechanical purification would be unlikely to dislodge it. Partaking in this manner of the physical properties of a vapour or of fine dust, it is clearly hopeless to attempt to combat the virus by non-volatile solids or liquid disinfectants, such as charcoal, chloride of zinc (Sir William Burnett's fluid), solutions of metallic salts, and similar substances.

What is wanted for this and all contagious diseases is a volatile and liquid disinfectant which, after first acting on the excreta, the floors, wall, &c., will, by its quality of gaseous diffusion rise into the air, enter the lungs of the animals, pervade the whole building, and attack the hidden germs of infection which otherwise would escape.

The disinfectants, particularly recommended by Mr. Crookes are the sulphites and carbolic, and we would add chloride of lime.

**LOCAL ANÆSTHESIA BY FREEZING.**—Rhgolene is the name used by Dr. Bigelow (Massachusetts Medical College) to designate the most volatile portion of petroleum naphtha. It boils at 70° F., and is the lightest of known liquids, having a specific gravity of 0.625. Kerosolene, it will no doubt be remembered by the readers of THE PRESS, was introduced by Dr. Bigelow some few years since as an anæsthetic by inhalation. Kerosolene was a petroleum product boiling at 90° F. Ether vapour, says Dr. Bigelow, reduces the temperature to 6° below zero F. The mercury is easily depressed by rhgolene to 19° below zero F.

**SESQUISULPHIDE OF CARBON.**—M. O. Loew describes a sesquisulphide of carbon  $C_2S_3$ , or as he formulates it,

He says that it is constituted similarly to oxalic acid, into which it is directly convertible. It is a brown solid, decomposable by heat into sulphur, which volatilizes, and a bulky carbonaceous residue.

**RECENT RESEARCHES UPON GLYCOGEN.**—Glycogen, which is well known to physiologists under the name of animal starch, or dextrin (the first term being the preferable one), occurs in the liver of most animals, and also in the placenta. It constitutes a considerable proportion of the tissues of the embryo. The chemical properties of this important substance and its physiological relations

have been carefully investigated by Bernard, Harley, McDonnell, Pavy, Schiff, and others. It bears an extraordinary resemblance as regards its chemical and physical properties to vegetable starch, except that it is amorphous and destitute of organic structure. It is white, inodorous, and tastes like starch; it is coloured, brownish, or violet on the addition of iodine, the solution becoming decolorized on warming, but regaining its colour again on cooling. It is converted instantly into sugar by the action of saliva, and into dextrine by the action of heat.

Mr. Michael Foster has found glycogen in the tissues of entozoa.

Although glycogen has been found by various observers in the tissues of many of the invertebrata, no one, as far as the author knew, had noticed the very remarkable amount which may be obtained from some of the entozoa.

The following remarks apply only to the round worm (*ascaris lumbricoides?*) which dwells in the intestines of the common pig. By mincing and boiling in water, with a drop of diluted acetic acid, one of these animals, a decoction was obtained which remained milky-looking and opalescent after several filtrations, and therefore at once suggests the idea of glycogen. This milky fluid strikes a deep port-wine red with iodine, the colour disappearing on the application of heat, and reappearing on cooling. It gave no reduction when boiled with the alkaline copper solution; but when treated with saliva at 35° C., the opalescence disappeared, leaving a fluid either perfectly clear, or exhibiting only a few flakes or a slight cloudy deposit of some albuminoid material, it containing much sugar, which was shown both by the copper and fermentation tests. In the *ascaris* little or no glycogen is to be found in the intestine, a small quantity in the generative apparatus, and a very considerable quantity in the spongy visceral tissue; by far the largest amount exists in the firmer muscular parietes. I failed to detect with iodine any distinct histological localization. It seems singular that an animal living in the midst of a fluid, one of whose chief functions is to change starch into sugar should thus be found amassing glycogen within its own body. The possible use of this glycogen is a matter of interest. Intestinal worms, inasmuch as they are animals and live, must needs consume oxygen. The amount of that gas they find in the intestinal juices, however, is very small, and having a constant temperature secured to them by warmth external to themselves, they are the very last of creatures to need what has been called "respiratory or calorific material." Whatever be the use of sugar, starch, or glycogen in the mammalian body, no "respiratory" use can be safely suggested for the large amount of glycogen occurring in the *ascaris*. Its abundance in the muscular parietes might suggest that it was material on its way to become muscle. If so, since the animals the author studied were adults, and ova-producing, the analogy of their glycogen would be, not with the glycogen of the muscles of the early mammalian embryo, but with the glycogen, or dextrine, occurring in smaller quantities in the full-grown muscles, unless one were to push an idea and say that the tissues of the lower animals were chemically homologous with the embryonic tissues of the higher ones. Dr. R. McDonnell has lately pointed out, in a paper read at the French Academy, the following facts in connexion with animal starch:—He says that, contrary to the opinions of some physiologists, there is no more starchy matter in the liver of animals fed on gelatine than there is in that of those which have been starved, these remarks being made in connexion with the subject "Relation of Starchy Matter in the Liver to Food." The quantity of amylaceous matter which the hepatic organ contains bears little proportion to the weight of the liver as compared with that of the body. The volume of the liver of a cat in a state of health and fed on flesh is nearly double that of the liver of a dog, during the most active period of the digestive process, nevertheless the liver of the cat in a state of health and fed on flesh possessed only about two-thirds of the starchy

matter produced by the liver of a dog which had been fed on carrots and bread. Hence it may be concluded that the saccharine form of food gives origin to the amylaceous matter much more easily than nitrogenous food. The liver can, however, prepare the amylaceous substance from the fibrine of the blood, the gluten of corn, and also from fresh meat.

**ANATOMICAL PREPARATIONS.**—M. Ferrere recommends benzole for preserving morbid specimens. We cannot see the advantages to be derived from the use of this substance. In its general properties it would resemble turpentine, but with these disadvantages, that it would be liable to become coloured unless very highly rectified, and would be much more volatile—two properties, either of which would be detrimental to the preservation of specimens in good order.

**SULPHUR IN GAS.**—Dr. Letheby, in his evidence given before the Committee of the House of Commons, gave a table of the illuminating power and grains per 100 feet of sulphur of the gases of the most important towns in the United Kingdom. The value of gas may practically be viewed as dependent upon these two items. The illuminating power represents the money value, whilst, as sulphur is the most deleterious impurity found in gas, both as regards our health and its injurious effects upon property, it is necessary to have as small an amount of that substance as possible. But in looking over the tables given by Dr. Letheby, we are sorry to see that frequently the relative position of these two points are in inverse ratio to what they should be, and that as the percentage of sulphur increases the illuminating power decreases. In the large towns, such as Birmingham, Liverpool, Manchester, &c., we find the illuminating power great, but also a large percentage of sulphur. The increased illuminating power of gases in these places can be well understood, as it is no doubt due to competition, and the absolute necessity for good lighting in manufacturing and commercial districts; but still they do not seem to be alive to the importance of the absence of sulphur—a matter of serious danger to their goods, if they have no regard to their lungs. The gas in "Pusey" may be taken as a fair specimen. The illuminating power was put at 16.49, and it contained 3.3 grains of sulphur in every 100 feet.

Chatham may be viewed as an example of a bad specimen of gas, as its illuminating power was put at 8.46, and yet it contained 18.2 grains of sulphur in the 100 feet. It is a pity that Dublin cuts so sorry a figure in this respect.

Dr. Letheby gives the illuminating power of the Dublin gas as 14.3, and says that it contains about 18 grains of sulphur in the 100 feet (17.92). He attributes the large amount of the sulphur in the gas now in use to the substitution of oxide of iron in the purifiers instead of lime, the removal of the refuse lime from the purifiers being considered a nuisance by those residing in the neighbourhood of the gas-works; but we question if the pouring of eighteen grains of sulphur, which is equivalent to fifty-five grains of sulphuric acid, during the combustion of 100 feet of gas, will not be more deleterious in the long run than any local nuisance. Until a better mode of purifying the gas from sulphur than that now in use be devised, we should advocate a return to the lime purifiers. We believe that gas engineers wash the gas with the ammonia water, by which means a considerable percentage of sulphur is removed.

**ON THE FERMENTATION OF URINE.**—In the spontaneous fermentation of urine, M. Béchamp says that, independently of carbonates of ammonium, alcohol, acetic acid, benzoic acid, and butyric acid are formed. The author has distinguished at least three forms of the genus *vibrio* attendant upon this fermentation.—*Bulletin de la Société Chimique.*

**PRESERVATION OF FRUITS, VIANDS, &c.**—M. Shaler proposes to employ dry carbonic anhydride (carbonic acid gas) for this purpose.—*Bulletin de la Société Chimique.*

## Abstracts of the Scientific Societies.

**GEOLOGICAL.**—May 23.—Professor A. C. Ramsay, V.P., in the chair.—The following communications were read:—"Notes on the Geology of Mount Sinai," by the Rev. F. W. Holland.—"On a New Genus of Phyllopodous Crustacea from the Moffat Shales (Lower Silurian), Dumfriesshire;" "On the oldest known British Crab (*Protocarcinus longipes*, Bell, M.S.), from the Forest Marble of Malnesbury, Wilts;" "On the Species of the Genus *Eryon*, Desm., from the Lias and Oolite of England and Bavaria," by Mr. H. Woodward.—"Notes relating to the Discovery of Primordial Fossils in the Lingulafags in the Neighbourhood of Tyddynglwadis Silver-lead Mine," by Mr. J. Plant.

**LINNEAN.**—May 24.—Anniversary Meeting.—G. Bentham, Esq., President, in the chair.—The Treasurer, W. W. Saunders, Esq., read the financial statement, by which it appeared that there was a balance in favour of the Society on the year's account of £213 12s. 4d., derived principally from the increased sale of the Society's publications and a large influx of new members during the past year. This being the day appointed by the Charter for the election of council and officers, the following gentlemen were elected members of the Council in the room of others going out—viz., Messrs. J. W. Dunning, R. Hudson, J. G. Jeffreys, W. Carruthers, and Colonel Munroe. G. Bentham, Esq., was re-elected President; W. W. Saunders, Esq., Treasurer; and G. Busk and F. Currey, Secretaries, for the ensuing year.

**ZOOLOGICAL.**—May 22.—Mr. Sclater made some remarks on a rare American Monkey from Demerara (*Pithecia leucocephala*), lately presented to the Society by Mr. W. H. Barton.—A communication was read from Mr. J. Y. Johnson, describing a new species of Berycioid Fishes from Madeira, proposed to be called *Trachichthys Darwinii*. A paper was read by Mr. H. Adams, describing fifteen new species of shells from Formosa, collected by R. Swinhoe, Esq., H.M. Vice-Consul in that island.—Dr. J. E. Gray read some notes upon the specimens of Tortoises from South America in the collection of the British Museum.—Dr. Gray also made some remarks on the specimens of Porcupine (*Hystrix*) in the gardens of the Society and in the British Museum, and pointed out the characters of a supposed new species of this genus living in the Society's gardens, which he proposed to call *Acanthion Grotei*, after Mr. A. Grote, by whom the specimen in question had been presented to the menagerie.—A communication was read from Professor A. Newton, "On the Species of Birds of the Madagascarian genus *Bernieria* of Bonaparte."—Mr. P. L. Sclater exhibited and made remarks on six new passerine birds from America, belonging to the sub-order Oscines.—Mr. Flower exhibited some insects captured in the Atlantic on board the ship *Hotspur*, about 300 miles from land.

**SOCIETY OF ARTS.**—May 23.—W. Hawes, Esq., Chairman of Council, in the chair.—The paper read was, "On Granite Working," by Mr. G. W. Muir.

**MATHEMATICAL.**—May 21.—Professor De Morgan, President, in the chair.—The following gentlemen were elected members:—Professor W. J. Adams, Messrs. O. J. Downes and A. W. Young.—Professor Smith read a paper "On a Formula for the Multiplication of Four Theta Functions."

### ON THE REDUCTION OF DISLOCATIONS OF THE SHOULDER BY SCHINZINGER'S METHOD.

PROFESSOR DUMREICHER brought Schinzinger's new mode of reducing this dislocation under the notice of the Vienna Medical Society, having of late had several occasions of proving its efficacy. Its simplicity and the small amount of force required for its execution are its chief recommendations as compared with other methods. An assistant having fixed the shoulder by crossing his hands over it, the operator

takes hold of the upper arm and rotates it outwards to such an extent that its inner surface is brought round in front, also pressing the elbow against the trunk as much as possible. A second assistant having placed his forefinger on the inner side of the head of the bone, pressing it somewhat outwards, the operator now presses the humerus against the acetabulum rotating it slowly inwards, and the head of the bone slips into its cavity with a loud noise. In three cases which had recently occurred in his practice, Professor Dumreicher, the reduction performed without anaesthetics, was effected by the exertion of very little force and without inducing any pain. Professors Roser and Bardeleben have objected to this method, that the strong rotation outwards might easily, in the case of adhesions existing, give rise to fracture of the humerus. There might certainly be some danger of such an occurrence if this rotation were performed in a very old dislocation, unless the adhesions had first been loosened by traction.

In the discussion which followed, Professor v. Pitha directed attention to Richet's method, which is of easy accomplishment by the exertion of little force, providing the muscles can be kept in a relaxed condition, and the patient's attention so occupied that he does not offer any resistance. The hand is passed into the axilla and an endeavour is made to surround the dislocated head by the fingers, which can be easily done unless the patient offers resistance. Indeed, the whole of the head need not be surrounded, for if the fingers can be planted into its larger circumference and slight traction be made on the head, the reduction may be accomplished. The force employed is so very slight that if the head is seized even by the left hand it may be reduced and neither preparations nor assistants are required. It is only necessary that the arm should be kept abducted in an easy position. This method succeeds even in very muscular subjects. As to Schinzinger's method v. Pitha recommends that it should be confined to recent dislocations; for, employing external rotation in a case of old dislocation, but to a less extent than here recommended, a cracking was produced, not from fracture of the bone, but from rupture of the tendon of the triceps. Dr. Dumreicher quite agreed that this plan must be resorted to only with great prudence for old dislocations. With respect to fractures occurring during reduction of old dislocations, he is of opinion that these are often the consequence of periostitis, to which repeated attempts at reduction have given rise. Such cases have repeatedly occurred at his Klinik. Professor v. Pitha added that Richet's method was especially indicated in cases in which fracture complicated the dislocation.—*Allgem. Wien. Med. Zeit. and Brit. and For. Med. Chir. Rev.*

### TWO CASES OF CROUP SUCCESSFULLY TREATED BY FUMIGATIONS OF SULPHURIC ETHER.

THE *Montreal Gazette Medicale* publishes from *Abeille Medicale* the report of two cases of diphtheritic angina, or false membranous croup, treated with success by inhalations of ether, under charge of Dr. M. Besson.

The first patient was a girl, six years of age, who presented the following symptoms: swelling of the sub-maxillary glands, puffed face, pulse slightly accelerated, pain in the throat, difficulty of swallowing. Mucous membrane of fauces engorged and reddened, tonsils strongly tumefied, and presenting several patches of the pellicular exudation which characterizes diphtheritic angina. Voice gone; cough dry, choking, and croupy. Respiration short, accelerated, and laboured. The patient was at first treated in the usual manner by vomits of tartar emetic and ipecacuanha, &c., chlorate of potassa, mercurial frictions around the neck—with no effect, however, except the expulsion of some membranous shreds and patches. As a *dernier ressort*, Dr. B., thinking it inadvisable to resort to tracheotomy, inhalations of ether were employed. The effect was an attack of suffocation, accompanied by a violent respiratory struggle, lasting nearly a minute, during which a false membrane, over six centimetres in length, and three millimetres in thickness, very dense, like a piece of parchment, was expelled. The effects of this paroxysm gradually subsided and the patient soon went into a calm sleep. After about eight hours, the symptoms recurred, and again recourse was had to the ether fumigations, resulting in further expulsion of false membranous exudation. Calm and sleep again supervened, the croupy symptoms yielded, and in a few days complete recovery had taken place.

The second patient was a little boy, five years of age, who

was attacked with diphtheritic angina. Vomits of sulphate of copper, &c., had been used, followed by the expulsion of some false membrane, but still the symptoms became aggravated. There was complete aphonia, tonsils tumefied, and covered with whitish patches, cough insonorous and choking, successive dyspnoea, convulsive movements of the expiratory muscles, quick, sibilant inspiration, face congested, eyes injected, jugulars distended, extreme anxiety, convulsive agitation, and intense fever. In short, the patient was in the midst of these terrible paroxysms, which have hardly any remission, and which announce that the final symptoms of asphyxia are near at hand. In this condition the patient was made to inhale, in the space of several minutes, about five drachms of vaporized ether, and soon afterwards, in the midst of the violent efforts of a veritable strangulation, he expelled, enveloped in thready mucosities, a false membrane seven to eight centimetres long, two centimetres in its greatest circumference, and very dense. In half an hour the symptoms of amelioration had become so decided, that the disease was thought to be broken, and during the forepart of the night the little patient rested quietly. Towards midnight the dyspnoea and the paroxysms became again urgent and violent, so that the patient himself cried for the use of the ether. This second fumigation produced the expulsion of several pieces of false membrane, rolled upon themselves, but smaller than the previous one. Again, subsidence of the croupy symptoms, and their occasional re-occurrence during the next two days, when the ether was again applied. The patient finally recovered.

The evaporation of the ether in these cases was accomplished by very simple means,—placing a bottle containing the ether, and terminating in an extemporized tube, into a bowl of water of 40° Cent.; the ether fumes were thus carried from the tube with the air of inspiration into the air passages.—*Phil. Med. Rep.*

## Reviews.

RESEARCHES ON THE MEDICAL PROPERTIES AND APPLICATIONS OF NITROUS OXIDE, PROTOXIDE OF NITROGEN, OR LAUGHING GAS. By GEORGE J. ZIEGLER, M.D., Physician to the Philadelphia Hospital, &c. Pp. 66. Philadelphia. 1865.

This little volume contains a number of details respecting the nature, preparation, and therapeutical properties of the well-known substance generally called laughing gas, the physiological operation of which was first experimentally proved by Sir Humphry Davy. That eminent chemist, as will be remembered, commenced his splendid career by an attempt to render different gases, only then beginning to be known to the scientific world, useful as medicinal agents, but the results were not very successful. Of late years, however, the nitrous oxide has been used as an anæsthetic in America, and Dr. Ziegler thinks that it will be found much more useful in therapeutics than has yet been supposed. But he gives no special cases in proof of his opinions, although he promises to communicate his experience at some future time.

ON THE SAFE ABOLITION OF PAIN IN LABOUR AND SURGICAL OPERATIONS, BY ANÆSTHESIA WITH MIXED VAPOURS. By ROBERT ELLIS, Surgeon-Accoucheur to the Chelsea, Brompton, and Belgrave Dispensary, &c. Pp. 80. London: Hardwicke. 1866.

THE MYSTERY OF PAIN: a Book for the Sorrowful. Pp. 101. London: Smith, Elder & Co. 1866.

ALTHOUGH the titles of these two little books appear to refer to the same subject, the scope and tendency of each is entirely different from the other. The object of Mr. Ellis is to show how pain may be most safely alleviated by anæsthetic vapours administered to patients by means of a peculiar mechanical contrivance of his own invention; the author of the "Mystery of Pain" treats the subject altogether in a moral and religious light, and without any

reference to the special exigencies of surgical or obstetrical practice. As the latter work therefore has little or no bearing upon medicine, we may dismiss it with a word of commendation for the principles it inculcates, and for the spirit of piety by which it is pervaded.

Mr. Ellis, after joining in the general commendation of the use of anæsthetics, and especially of chloroform in obstetric practice and in surgical operations, expresses his feeling of insecurity in the use of unmixed chloroform. The risk, although small, undoubtedly exists, and he thinks that by a judicious modification of the nature and quantity of the anæsthetics employed, and by the adoption of particular instruments in their administration, all danger may be avoided. He quotes from the Report of the Committee on Chloroform lately appointed by the Medico-Chirurgical Society, and from other documents, to prove the danger often attending the use of pure chloroform; and agreeing generally with those who recommend the conjoined use of alcohol, ether, and chloroform, he inculcates the necessity of great care in the selection of these fluids, which in commerce are often found either adulterated or of insufficient strength.

Mr. Ellis concludes, from the result of experiments, that the effect of chloroform is to lower the power of the heart, and in a sudden strong dose even to paralyze it at once, while ether, on the other hand, acts chiefly on the respiratory functions, and not upon these until after inhalation has been carried on to a very considerable extent. Thus it is fair to suppose that chloroform and ether in proper combination will neutralize each other, the latter furnishing to the heart the stimulus required to enable it to resist the action of the former. Mr. Ellis also attaches great importance to the amount of alcohol vapour administered, this agent being useful in stimulating and sustaining the action of the heart. In the apparatus he has devised, he effects the vaporisation of a sufficient quantity of alcohol to produce a sensible effect in inhalation, by a fringed arrangement resembling the gills of a fish, by which means a very large extent of surface is exposed within a small compass. Another feature of Mr. Ellis's apparatus is, that the condition of the person who breathes the vapour may be controlled by the finger of the operator; thus he may be slightly excited in the first instance, then the sense of pain may be benumbed or destroyed, and lastly full anæsthesia may be induced. Plates are given showing the construction of the apparatus recommended. Mr. Ellis concludes his book by stating his conviction that chloroform ought not to be given alone, as a rule, but in combination with a stimulant, and that there is no method of accurately administering it, either separately or in combination, but by some mechanical contrivance, and we may add that his instrument appears likely to attain the objects for which it is designed.

VEGETABLE CHARCOAL: its Medicinal and Economic Properties, with Practical Remarks on its Use in Chronic Affections of the Stomach and Bowels. By JAMES BIRD, M.R.C.S. Cheap edition. Pp. 90. London: Hardwicke.

At a time when simple remedies are being tested as antagonists to disease, when the properties of air and water, and light, as preservers of health, are becoming more and more generally recognized, it is only right that carbon, of which in London, at least, we seem to have too much in the form of vapour, should receive a word of commendation as a medicinal agent. Even London smoke has its hygienic mission in destroying or neutralising principles far more noxious than itself, and when introduced into the stomach, as recommended by Mr. Bird, it possesses indubitable efficacy in relieving some of the disordered conditions of that viscus. Mr. Bird's pamphlet deserves to be extensively read, and the very small price at which it is sold, will make it accessible to all classes.

### MEDICAL EDUCATION AND THE MEDICAL COUNCIL.

MANY of the shortcomings of the Medical Council, and many of the failures which it experiences, are due not so much to erroneous, or extravagant, or interested views on the part of its members, as to the nature and the terms of the Medical Act from which the Council derives its origin, and the provisions of which the Council is appointed to carry into execution. That Act being a compromise among conflicting parties in the Medical Profession, and in some measure also a compromise between the profession and the homœopathic and other quacks, the measure seemed to resemble the bed of Procrustes in levelling all distinctions, in drawing out short people into long ones, and cutting down the long people into short ones, so as to make them all fit into one mould by assuming certain uniform dimensions. Added to all this, instead of making the profession govern the corporations, it allowed the corporations to govern the profession, and much of the conflict of opinion in the discussions has arisen from the ardour of contending parties in prosecuting the particular views advocated or adopted by the chartered bodies which send representatives to the Council.

Among some of the bodies which the Medical Act would have almost annihilated, if its provisions had been fully carried out, and if timely concessions had not averted the impending blow, was the Royal College of Physicians of London, and we confess to a feeling of something like mortification at the present altered condition of that ancient corporation, as compared with its former venerable, though somewhat frigid magnificence as the chief medical institution in the metropolis of the world. This College, although never rich, and disdaining for centuries to become a popular institution, was nevertheless in the very highest degree respectable, and even illustrious; and we are conservative enough, and perhaps old-fashioned enough to remember with reverence the time when Latinity was cultivated within its walls, and when a real University education was required as a *sine qua non* in the candidates for its honours. It is true that time sweeps away many of our prejudices and demolishes some of our most cherished idols, and the literature and the science of our own country as well as those of France, Germany, and Italy, have supplanted the dicta of the sages of Greece and Rome, and have enshrined perhaps much more practical and useful medical knowledge than is to be found in the writings of the ancient world. Still we cannot but regret that the College of Physicians has been so pressed by necessity as to give up by degrees its former high standard of scholarly

requirements, and to float so readily with the stream of some modern opinions as almost to drop its classical pretensions altogether.

The College of Physicians instead of being what it once was, the *facile princeps* of all British Medical Institutions, is now obliged to take its chance with the rest, and join in the general scuffle for medical candidates. Not that we assert that the College has made any unworthy concessions, or that its examinations are not conducted with fairness, impartiality, and completeness; but still we cannot help concluding that, if the Medical Act had not passed, and thus practically levelled the College of Physicians with all the other Medical Corporations, the College would have gone on in its ancient somewhat lofty style, and would have disdained to soil its fingers with receiving money from candidates for general practice. One proceeding on the part of the College was, we conceive, deserving of censure—namely, its admission, without examination, for a small sum of money in 1859, of a great number of members, whom it had formerly excluded from its walls; an act which was grossly and monstrously unfair to those who had in former years paid large sums for the honour of the membership, and had besides submitted themselves to the very stringent and comprehensive examination which was then conducted. The only excuse for the College was no doubt the plea of necessity, and it must be admitted that it did not go the length of the sister institution in a northern city in actually selling its diplomas, for all the members admitted by the London College were already in possession of degrees, while in the other instance to which we allude, admission was granted on much easier terms.

Now the Medical Council is intrusted with the Herculean task of making all the Corporations fit into the Procrustean bed; so that if any one of the licensing and examining bodies endeavours to enforce a superior education, it finds itself tripped up by others which are not so particular, and the Council has no power to make any distinction. The College of Physicians of London, the University of London, the English College of Surgeons, the London Apothecaries Society, the Universities of Oxford and Cambridge, are all the same in the eye of the law, so far as medical qualifications are concerned, although the mode of education and examination conducted by these bodies is and must remain, in many respects, essentially different.

But whatever the advocates of the so-called "one-faculty" scheme may think, we believe it quite unadvisable to insist that boys intended for the Medical Profession should proceed to Oxford or Cambridge at fourteen years old, in order that their curriculum of medical and general education should be completed at twenty-one, as may be done and must be done at Apothecaries' Hall, to suit the exigencies of the public; and on the other hand, we maintain that a person who has delayed his entrance into the Profession until he is twenty-two or twenty-three years old, because he has spent more

time, more money, and more labour on the acquisition of learning, deserves to hold a somewhat better position than his younger and less accomplished rival. Both perform, and perform well, their allotted tasks in society, but it is downright folly to level both together, and thus to discourage the scientific study of the Profession.

We conceive that this plan of general levelling is one of the greatest defects in the Medical Act, and that it practically obstructs all attempts to enforce a high class medical education.

### THE LONDON WORKHOUSE INFIRMARIES AGAIN

"Why is it," writes the *Times*, in a recent sensation leader, "That with a department (the Poor-law Board) established to protect both ratepayers and paupers, especially charged with the duty of checking abuses, and provided with an ample staff of officers for no other object, we are left to learn from the voluntary information of a nurse the wholesale inhumanity that is being practised in some of our workhouses under the outraged name of charity?"

This spirited language addressed to the Poor-law Board is suggested by the details of an inquiry which has been held upon some proceedings in the Strand Union Workhouse, and presided over by Mr. R. B. CANE, one of the Inspectors of the Poor-law Board, who, by the way, has not long ago distinguished himself by opposing Mr. GRIFFIN'S conscientious and praiseworthy labours for Poor-law Medical Reform. The case against the Strand Union officials is a capital one, and is precisely what was wanted to bring the whole question of workhouse abuses in a prominent form before the public, for it happens here that there is no particular case of individual ill-treatment to be investigated, and we may add there is no underpaid and overworked Medical Officer to be brow-beaten, censured, and abused. It is the whole system of workhouse mismanagement which is called into question, and the principal witness is a nurse, who does not appear to be actuated by any other motive than a desire to speak the truth, and who, fortunately for herself, has nothing to fear from the vengeance of the local Guardians or from the tender mercies of the Poor-law Board. The Medical Officer of the Workhouse, too, has spoken out, although, as he tells us, under the fear that his scanty salary may suffer from his boldness; but although the Strand Guardians, and Mr. R. B. CANE, and his employers, the Poor-law Board, would, we have no doubt, readily connive at the dismissal of this gentleman if it could be done quietly, yet we give all of them credit for not daring to outrage public opinion by such a proceeding, now that the matter is ventilated in the newspapers and in the Houses of Parliament. We do not think it necessary to go through the details of mismanagement in the Strand Union Workhouse; the appointment of aged and drunken and thievish and ignorant pauper nurses; the habitual neglect and robbery of the sick patients; the ineffectual remonstrances of the Medical Officer and the threats of

reduction of his salary and his fear of dismissal if he did not hold his tongue; the huddling together of the sick and the infirm in close and ill-ventilated rooms, and many other monstrosities. We knew it all already, and so does Mr. R. B. CANE, and so do his employers, the Poor-law Board; and we knew perfectly well that this well-paid official can keep his knowledge to himself when it suits him or them to bolster up the local Guardians. It is positively disgusting to witness the hypocritical and spasmodic zeal which the Poor-law Board and their Inspectors are now manifesting in behalf of the sick poor, and we have only to echo the sentiment expressed by the *Times*, as to the flagrant neglect of duty chargeable upon this Board, which we think is quite as blameable as the local Guardians, and even more so, for the latter are often ignorant and low persons, and are certainly unpaid for their services; while the officials of the Poor-law Board are educated men, some of them Members of Parliament or hangers on of the Government, some of them appointed to their places by patronage, and the subordinates by competitive examination and patronage combined, and they are all amply paid for the discharge of duties which it now turns out they have never hitherto properly performed.

As we are writing, the *Times* has come out again with the following denunciation of the Poor-law Board, in ever word of which we heartily concur, and we may add that when the inquiry as to the working of Poor-law Inspection takes place, Mr. R. B. CANE will have personally plenty to answer for:—

"There is one plain question which the public is bound to press home, again and again, before the impression made by these disclosures has passed away. What is our Poor-law Board about if it fails to discover such enormous and patent defects in the management of metropolitan workhouses, and what is it worth if, knowing them, it fails to enforce a remedy? The heartless indifference of parochial busybodies to the wants of the suffering poor may be more shocking to our feelings, but it is not so humiliating to our system of government as the default of the very department which is maintained for the sole purpose of controlling local administration. We have a staff of twelve Poor-law Inspectors, each provided with a clerk at the public expense, whose special business it is to find out and report the weak points in each workhouse and district, yet we are indebted to voluntary agency for the knowledge of horrors which it makes our blood boil to read. But for the *Lancet* Commission, and the Association that has growing out of it, we should not yet have been aware that poor men and women, dependent on our national charity, are left to lie down and die almost unheeded, and with all the thousand needs of illness unsupplied, in institutions superintended by the Poor-law Board, and supposed to be under the immediate eye of independent Visiting Committees. It is not as if the evils now brought to light were recondite or easy to conceal; they would at once strike any competent person who should walk through the wards. We are told, on good authority, 'that where the most gross mismanagement and excessive abuses have been discovered by medical inspectors within a few hours the Visiting Committees have been most regular in their attendance and systematic in their reports.' If this be true, it is time to institute such an inquiry into the working of Poor-law Inspection as may satisfy us that worse than what we already know does not remain behind."

A DISPUTE has occurred between Drs. Bonney and Button, which has been referred to the Southwark Medical Association.

## THE VIS MEDICATRIX NATURÆ IN THE DISEASES OF CHILDREN.

IN these days when the respective merits of different medicinal agents and methods of treatment are so keenly discussed, there is, we think, a tendency to ignore, or at least to undervalue the efforts which Nature herself puts forth to rectify morbid conditions and cure disease. When a few years ago the great bloodletting controversy shook the ranks of the profession and broke them up into contending companies, attention was aroused to the fact, that patients attacked by acute inflammation did not succumb although depletion was not had recourse to, but on the contrary made speedier recoveries than those who were bled, and the result was that there was an immediate revulsion towards what has been called "the expectant plan" of treatment. The lancet, salivation by mercury, depressants, and all drugs of a violent kind were given up, while their places were taken by tonics, stimulants, and a liberal diet. We are rather inclined to think, however, that there is now a spirit growing up in many quarters which is striving to drive Nature again into the shade—a spirit which has taken its origin in that insatiable longing after new remedies and fashionable preparations, which characterises the age. Taken possession of by this desire for novelty, impatient and jealous perhaps of the "vis medicatrix naturæ," and concussed into doing something when it is only necessary to stand by and observe, the practitioner is too often led into prescribing remedies which only complicate and confuse the symptoms of disease. We know of nothing which illustrates more clearly the error and utter folly of such conduct, nothing which can demonstrate more forcibly how great the restorative powers of Nature are, than an attentive study of the diseases of early life. It is there more than in the affections of adults that one may learn how great the tendency is of almost all maladies to terminate in recovery and health.

To learn this important lesson aright, however, it must be studied at an hospital; in one of those institutions which in recent times the kindly benevolence of the public has opened for the reception of sick and suffering children. For anywhere else, even in the best regulated homes, the patients are never so thoroughly under our control; out of an hospital many little things are done by affectionate friends which would not be permitted there, and too frequently the doctor's orders are not carried out with that precision and regularity which are so indispensable to accurate observation.

The wonderful efforts made by Nature to overcome the disease which has seized upon the system, are perhaps most striking as witnessed in the fevers of childhood. To watch from day to day the struggle that is waged—how almost every organ in the body labours to throw off the morbid influences which are operating injuriously on the constitution—how gradually these efforts are attended by success, till through the united and harmonious action of lung and liver, kidney and skin, the blood is once more purified, and the little sufferer passes from the hot frenzy of fever into the cool calm happiness of health—is a study which is full of interest and instruction.

In simple uncomplicated cases of febrile disease we now know that very little in the way of treatment is required, and that, provided the child be placed in favourable sanitary and hygienic conditions, the fever will run

its course to a favourable termination. There is no need to trouble the young patient with frequent and nauseous doses of physic, for milk and some simple cooling drink will, in such cases, be all that Nature requires to set things to right.

Then, again, how many of the nervous affections to which children are liable get better without the administration of drugs?

We know, for example, that chorea—a disease so generally regarded by parents with great alarm—often disappears entirely if the patient is removed from excitement and undergoes a little moral treatment. We have over and over again seen the spasms and twitchings removed and perfect steadiness regained under the use of the cold douche alone.

A pneumonia will generally terminate in recovery without blistering or bleeding, if the vital powers be sustained and some gentle stimulus given to the eliminating organs. The truth of this we are glad to see admitted by Dr. West in the last edition of his valuable work on the "Diseases of Infancy and Childhood," for in former editions bleeding and antimony were recommended.

Dr. Dickinson of London, has shown that albuminous dropsy frequently gets well under full doses of distilled water alone, which appears to act by washing out the kidneys; and we have ourselves pursued this plan in numerous cases of post-scarlatinal dropsy with success.

We might go on enumerating many other affections which, as a rule, get better without the use of active medicinal agents, but we shall only give another illustration. Some time ago a pale, unhealthy looking boy came under our care, suffering from bronchitis. His breathing was rather hurried, and he had slight cough. Auscultation of the chest revealed large moist rales, and over the heart a distinct loud double friction murmur, so harsh as to resemble the rubbing together of two pieces of sand paper. The pulse was quick, but as the boy was not suffering at all quiet and rest in the recumbent posture were enjoined, and fomentations were applied to the chest. Under this treatment the friction sounds entirely vanished, and the patient in a short time got completely restored. Here were symptoms that were calculated to awake alarm, and would undoubtedly have led to very active treatment had the boy come under the care of most medical men. Yet with the simplest precautions the case terminated in health. What we contend for, therefore, is, that Nature should be more trusted, and less interfered with, especially in the treatment of the diseases of early life. It is because of a lack of confidence in her recuperative powers, and a restless desire to be "doing something," that practitioners will not become more simple in their dealings with disease. We know that in thus writing we may draw down upon us the disdain of those who will likely regard us as belonging to that class in the profession who would introduce into general practice a "do-nothing" system. But we hold that it is a very different thing for a medical man to stand by the bedside, an intelligent observer of Nature's operations, ready when he sees she is hard pressed to come to her aid with the appropriate remedy, yet not rudely interfering with her efforts and to stand by listless and heedless, and doing nothing at all. For in the former case he may, by his well-timed help, turn the balance which trembles between death and recovery, while in the latter, the result, whatever it may be, is effected without and in spite of anything that he has done.

What we desire to see is a simpler and more philosophic

treatment substituted for that blind routine which yet too widely prevails. But this desire we do not hope to have realized till the attention of our students and junior medical practitioners is more closely applied to the study of that large and important class of diseases which are peculiar to the opening years of life. For we believe that it is in this way that clear and accurate views of the immense powers of Nature to resist and overcome disease can best be attained.

### THE EDINBURGH VETERINARY SCHOOL.

IN our last week's issue attention was directed in the leading columns to the present position of the veterinary school, and the serious damage to her interests that would result should Mr. Holland succeed in carrying his bill through Parliament. We are glad to be able to announce that every exertion is now being made to secure to the Edinburgh College the right to grant diplomas; and Mr. Stevenson, the able conductor of the *N. B. Agriculturist*, is now in London endeavouring to obtain this boon from Government.

It is seldom that any Medical Journal devotes its editorial pen to a notice of a Medical Work, and still more rare for our autocratic contemporary, the *Lancet*, to go out of its way to damn a book in large print. That task is usually confided to the reviewer, and any supplementary opinions are restricted to the limits of correspondence, real or imaginary, or the small type of "Notices to Correspondents." It appears, however, that Dr. FOSTER of Birmingham, whose work on the "Spymograph" we reviewed the week before last, has hit upon some "pet corn" of our contemporary with so acute a sting that a bitter cry comes out. Dr. FOSTER's book is reviled as "scarcely more than a collection of cuttings" from M. MAREY's work, and its author is accused of having plagiarised the labours of Dr. ANSTIE, and represented himself as the first writer on the subject in Great Britain.

The reviewer of Dr. FOSTER's work for THE MEDICAL PRESS AND CIRCULAR assures us that these charges are utterly groundless, that Dr. FOSTER in several parts of his brochure not only acknowledges Dr. ANSTIE's priority, but quotes his cases and opinions. Furthermore, that every line which was translated from M. MAREY's book was acknowledged by Dr. FOSTER and published with inverted commas, and that every one of the pulse traces, which form the most important portion of the book, are from Dr. FOSTER's own observations, and have never been anticipated by M. MAREY, Dr. ANSTIE, or any one else. The injustice of the *Lancet's* accusation is shown by the fact that M. MAREY himself has accepted the dedication of a forthcoming work on the subject from Dr. FOSTER, thanked him for his praise of his book and asked permission to quote in a forthcoming work the very observations which the *Lancet* says are "scarcely more than a collection of cuttings" from his own work.

We are certain the *Lancet*, having read its own condemnation and Dr. FOSTER's letter, will feel that the process of crushing out a young practitioner is little dignified even where there is a legitimate reason, and that in the absence of such causes it is not large-minded to

permit personal attacks on an author who may be so unfortunate as to infringe a monopoly. There is no journalistic despotism so strong that it can afford to despise the common rules of justice, equity, and courtesy. We may add that the opinions of the *Lancet* were not solicited by Dr. FOSTER, and that it is not true, as stated in that journal, that a copy was sent to the office for review.

### Our Weekly Retrospect of the Medical Journals.

JUNE 9TH, 1866.

THE *Lancet* refers to the coming election at the College of Surgeons, Lincoln's-in-Fields. Mr. Charles Hawkins and Mr. Spencer Smith are the two new candidates. Mr. Luke and Mr. Hilton propose themselves for re-election. Mr. Hawkins promises that, if elected to the Council, he will not seek to be appointed Examiner; consequently, our contemporary supports his candidature in opposition to Mr. Luke, who is said to have occupied his seat sufficiently long.

Dr. Lankester has been unfortunate enough again to have fallen foul of the medical profession in Dr. Sansom. The question of dispute at present lies in the custom of getting a receipt from the medical witness before he receives the fee, which latter is further curtailed by the abstraction of the shillings of the guineas by the coroner's officer.

The report of the Colonial Surgeon of Hong-Kong, Dr. Murray, describes the health of that town in 1865. The disease which proved most destructive, and that, too, among the native population, was a species of yellow fever, which is now as far as China is concerned.

Under the head of "Cacoethes Scribendi," the modern system of medical writing is contrasted with that adopted by our forefathers, very much to the disadvantage of the former.

An approver has turned up in Mrs. Beeton, late head-nurse of the Strand Union Workhouse Infirmary, who has been examined with reference to the disgraceful administration of this and similar institutions.

Dr. Hassall writes to the effect that the bran biscuits made for the diabetic are perfectly useless, as they contain twenty-eight per cent. of starch. He proposes a "flour of bran," this, when mixed with his "flour of meat," is about the best diet for the diabetic.

The first of Professor Hancock's lectures "On the Anatomy and Surgery of the Foot," at the College of Surgeons, is announced. He adopts the arrangement of Bishop in describing the bones. He alludes to the round elastic ligament filling up the space between the os calcis and scaphoid bones. He also proved, by the dissection of the fetus, that the sesamoid bones beneath the metatarsophalangeal articulation of the great toe, are not produced by pressure, but that they are developed in the tendons for a particular purpose. The whole lecture is well worth attention.

Dr. Pilcher relates a very curious case of a lunatic lady who was in the habit of eating large quantities of nails, stones, and crockery. They were retained in the intestines for ten weeks, and subsequently passed per anum without having caused much mischief.

From Guy's is related a case of croup in which tracheotomy was performed. The child died on the fifth day from hæmorrhage from the innominate artery, caused by pressure of the edge of the tracheotomy tube.

The *Medical Times and Gazette* devotes a leader to the practice in cholera. It regrets that Dr. George Johnson's theory is not reconcilable with the practical experience of the profession.

A case of suspected rinderpest in man has been recorded. Dr. Spencer Wells relates his 82nd case of ovariectomy.

## Correspondence.

### THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In these days of Congresses, Social Science gatherings, Council meetings, &c., one naturally looks for the results of the time and labour expended on them; and as there are many sceptics who narrowly scan the progress of each meeting, and the profit to be got from the long, and in most cases needless, debates on unimportant topics forms a theme for the sceptic and a butt for the searching marksman, whose aim is to scatter piteously to the winds the exalted imaginings of those who go up with enlarged ideas of their own individual mightiness and persuasive eloquence; to all of whom nevertheless we are bound to give the credit of intending to do something grand, even though it may afterwards turn out in "moonshine."

What, then, has been done in the last session of the General Medical Council? For the last three weeks I have read the reports of their proceedings in your excellent journal, and have arrived at this conclusion—which as far as I have been able to glean is very general among the profession—that very little has been done conducive to the welfare or the protection of medical men. I cannot say *nothing* has been done, because one or two insignificant measures have passed, to which significance has been given by their being inserted on the minutes, and several committees were also formed, each drawing up its own special report, which eventually turned up as a subject for a long and tedious debate. There were also some nice little speeches, interspersed with a few not very parliamentary expressions, almost tempting me to ask you, Mr. Editor, to what shall I liken this great Medical Council—"The Happy Family" one sometimes meets in the streets of London.

Comparisons are odious, but I trust you and the members of the Council will pardon me for this one.

Those who talk the loudest and indulge in all sorts of arrogant expressions are not generally the first to back up their remarks with proofs. Like the inhabitants of the cage of the "Happy Family," they will snarl and growl and bark at one another, each determined to have his own way at the smallest possible cost; they will appropriate each other's food, and if it happens a savoury piece is thrown in a general rush is made for supremacy. They all may and do snarl but few may fight, the dog may bark but must not bite; because it would be indecorous in a "happy family" to fight, besides there stands the superior whose baton might unluckily fall upon the head of the disturber of the peace. We are at no loss to perceive the millennium has not yet made its appearance, the lion does not lie down with ox, or the wolf with the lamb.

Turn, then, with me, Mr. Editor, for a peep into that assembly whose sittings are annually held in Trafalgar Square. Enter the noble hall, so kindly lent by the Royal College of Physicians, on the walls of which are hung the portraits of many of the *great men of the past*; cast your eyes downwards, and you will then see some of the *great men of the present*, sitting round the large table in the centre, with books and papers piled before them *en masse*; you ask yourselves the question—what measure will be the issue of all this? With the President's kind assent you shall stay an hour or so and listen to the debate. It may be on the "New Medical Act," the "Visitations of Examinations," or the fitting in of some necessary spoke to make the wheels of the profession run more smoothly.

Now, you will see the point of my illustration as you hear the big dog bark, and bark loudly too, and the spaniel joins issue; there is a bone of contention. What a mighty

chorus of voices, as they each nibble at this bone; even the little mouse has stolen his mite. Now they warm to their work, each seeming desirous to get a firmer hold of the bone than his neighbour. There is a pause, and you naturally imagine the one who has been making the most noise has got it all his own side; another fierce growl and he resumes his seat, being apparently satisfied within himself as to the results of his splendid attack.

Now, perhaps, you will hear something from the other side; one equally on good terms with himself will rise, and you may see the lion bearded in his den, his nose rubbed and scrubbed with his own vituperations by the tiger opposite, whilst poor Leo's paws are tied; and then you hear the chuckling of some of the little one's, and, hear, hear, will escape their lips, with perhaps a consolatory mew from the other side. Mr. President must stop this at once, and his authoritative voice is listened to with profound respect, the bantering and bickering must and does cease, after a storm comes a calm.

Now, having quitted the scene, some such thoughts as these will probably suggest themselves, as they have done to me. These Councils may be all very well for the display of oratorical powers, a capital school for instruction for those of the big guns, who aspire to shoot for oratorical honours, first-rate chances for these things at the expense of the profession. But, as *Punch* said in a recent number, "business is business." Therefore, the business of the medical profession executed at as little cost as possible, in the least possible time, and in the best manner, should be the primary study of the Council.

What has been done for our protection from the imposition of quacks who infest the metropolis and the provinces, robbing not only the pockets of the victim, but the registered practitioner of his legitimate claim? The major portion of the members of the Council are men with large practices, or with lucrative appointments at the universities; these, I maintain, are not the men who feel the grievances of the profession, they are above it. How, then, can we expect them to legislate upon questions they do not understand.

I trust, Mr. Editor, you will kindly allow space for this letter which may, perhaps, induce others to express their opinions on matters of such vital importance to the medical profession at large.—I have the honour to be, Sir, your obedient servant,

A SUBSCRIBER.

London, W.C., June, 1886.

### THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—As it appears from the proceedings of the Medical Council that the Home Secretary has in contemplation an Amendment of the Medical Act, and as the profession and the public have gained comparatively little from the deliberations of our medical parliament during the eight years of its existence, it may not be inopportune to inquire whether the failure be owing to any defect in the Act itself, or to something wrong in the machinery by which it is worked. Now, while I admit that the Medical Act may be improved by the alteration of some clauses and the addition of others, I contend that the present constitution of the Council is radically defective, and I believe that defect to consist in its being a representative body, for as long as it possesses its present representative character it never will be an independent body.

The proceedings of the Council at all its meetings prove this, and show clearly that self-interest influences the representatives of most of our medical corporations; and, accordingly, any change which is calculated to diminish the number of candidates for examination at our Universities (such as the introduction of Greek into the preliminary education of students) is sure to be vigorously opposed by

those members whose emoluments are likely to be lessened by the adoption of a more stringent curriculum. The difficulty of reconciling conflicting interests was strikingly illustrated in the case of the Pharmacopœia, the compilation of which occupied so much time, and which is now admitted to be anything but an improvement on its predecessors; if the compilation of this work had been intrusted to one or two competent men, it would have been prepared in a shorter time at less expense and with more satisfactory results. The recent passago-at-arms between Sir Dominic Corrigan and Dr. Alexander Wood furnishes additional proof of the hopelessness of expecting any harmonious action on the part of this strangely constituted body, and fully bears out your remarks in THE PRESS of the 16th ult., where you say the very constitution of the Council is of such a heterogeneous nature and represents so many conflicting interests that uniform action in any one direction seems to be utterly impossible; and, indeed, the Council themselves appear to be of the same opinion, for Dr. Acland is reported to have said that the constitution of the Council was extremely difficult to work, and, as an executive, almost impossible. No matter, then, what amendments may be introduced into the Medical Act, it appears to me that any efforts at reform by a Council constituted like the present must be necessarily abortive, and I would, therefore, suggest, as the only effectual way of remedying existing abuses and securing to the profession an impartial administration of the law, to abolish the Council and appoint a medical board of three or four eminent men similar to the Poor-law Board. The expense attending this arrangement need not be greater than is incurred by the annual meeting of our present councillors in the metropolis, while a board so constituted could enforce rules for the general good of the profession regardless of the usages of any particular corporation. Such a board would have no constituents to please, no personal interests to serve, and having no opportunity for oratorical display, could devote its attention to practical details, instead of wasting its time in unseemly altercation and angry debates.—Very truly yours,

D. B. O'FLYNN, M.D.

Carrignavar, June 9, 1866.

#### ELECTION OF COUNCIL FOR THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I do not address you to comment on the way in which you introduce me to your readers in the leader of your last issue, for they can judge of me by what I have written in your pages for the last few years, nor to refer to the active canvass which was made against me in the election-room of the College, for it proved unsuccessful; but I write in reply to a letter signed "B. Wills Richardson, F.R.C.S.I., Examiner in the Royal College of Surgeons, and Surgeon to the Adelaide Hospital." Its principle is contained in the following sentence:—"Now, I hold that a Council composed to any extent of medical tutors must eventually lead to the destruction of the independence of the Examiners, because those gentlemen, being in the capacity of tutor and elector of Examiners, and, at the same time, having the common privilege of attending the examinations, must, in virtue of that triple capacity, unconsciously exercise a kind of influence over many Examiners which might cause a bias in favour of a candidate that the College should most jealously endeavour to prevent."

These words imply suspicion of the honesty and the regard for a solemn oath of the present Examiners, or those Fellows who may succeed them, which, I think, wholly unwarrantable, and which, with respect to every gentleman who has filled the office for the last twelve years, I could refute by numerous instances of independence and disinterestedness. As I can discover in Mr. Richardson's letter

no direct reflection upon medical tutors, I do not submit a defence of that order, in the ranks of which I feel proud to say I have conducted myself in such a way as to gain its universal support at the election for Council.

In your leader you say, "Dr. Mapother's candidature was vigorously supported by a considerable number of the Fellows of a more junior standing, and would have probably been well received by the great majority of the electors, &c." I feel bound to test these assertions by the statistics of the ballot: 130 Fellows voted, but over 20 papers were cast, as the names of candidates for other offices were retained upon them. Several late Councillors, whose great claims for re-election were probably remembered by every elector, had 105 marks, while 71 were scored for me. Of those Fellows, who, having obtained their position by examination since 1845, may be distinguished as "junior," but 42 voted, so that, even if I had the support of every one of them, I must have also enjoyed the confidence of a considerable number of "seniors" to make a total of 71. Feeling that the Charter contemplated an annual election—not re-election of Council—I did not wait for what you term "an opening in the death or resignation of any of the existing Council;" firstly, because I would not calculate on the former deplorable or the latter unheard-of event; and, secondly, I am favourable to the practice of retirement by rotation, which is established in the London College of Surgeons, and nearly every public body.

The Council and Examiners count as thirty-two Fellows—a figure which approaches within two of what you call "a large number of Fellows, who, however, supported the ex-Council against all comers," if this quantity can be fairly obtained by the subtraction of my 71 votes from the 105 received by several of the ex-Councillors, who were quite unopposed. Your leader also implies that the contest was directed against the ex-President, Mr. Wilmot. This I deny on my own part and that of the other candidate for Council.

Having in this letter replied to statements which I could not suffer to remain uncontradicted, I will enter the Council-room on Thursday without the slightest feeling of regret for any act by which I achieve my election, or of acrimony towards those who opposed it, but with the sole object of using any energy I may have in the interests of the College.—Yours faithfully,

E. D. MAPOTHER.

#### ANALYSIS OF THE WATER OF THE RED SEA.

MM. ROBINET and LE FORT have lately analyzed a specimen of water taken from the Red Sea, with a view of discovering the cause of its peculiar tinge of colour. They found only very slight distinction between it and the water of other seas, except a larger proportion of the usual salts to the extent of 43.97 grammes per 1000, and a consequent increased density of 1.0306. The authors say:—

"This sea, which has been compared to a straight canal of 1000 miles long, is situated between banks of broiling sand in the middle of a country whose mean temperature is not less than 32° Cent., where neither river nor rain can compensate for the enormous and continued evaporation, and where the vapours which rise from the surface never return in any form. Under these circumstances it is not wonderful that the water of the Red Sea should be more highly saturated than that of the Mediterranean."

A CHOLERA HOSPITAL SHIP FOR THE THAMES.—The Lords of the Admiralty have granted the ship *Belleisle* for use in the Thames as a cholera hospital. It is to be under the charge of the Committee of the Seamen's Hospital Society, and will be moored in the neighbourhood of the *Dreadnought*.

The post of head surgeon to the Emperor of the French has been assigned the celebrated M. Nélaton.

METROPOLITAN COUNTIES BRANCH OF THE  
BRITISH MEDICAL ASSOCIATION.

EDWARD H. SIEVEKING, M.D., President, in the Chair.

DISCUSSION ON PUBLIC VACCINATION.

AN ordinary meeting of the Metropolitan Counties Branch was held at 37, Soho-square, on Friday, May 25th, at eight p.m. Twenty members and visitors were present.

Dr. B. W. RICHARDSON commenced by pointing out that members of the medical profession in considering the subject of vaccination, ought first to place themselves in the position of the public at large, and to respect many of what might be called the prejudices of the people. These prejudices, even though the result of ignorance, should not be severely criticised, but rather removed by reason and by judicious instruction. In many points bearing upon vaccination, medical men themselves required more light; and amongst them there was the widest difference of opinion as to the measures that were required to ensure a perfect and general system of vaccination. In considering vaccination in its legal bearings, it was a primary question, whether compulsory vaccination is really necessary? To ensure the success of compulsory vaccination, a purely despotic action must be sustained. In addition, there must be some test or standard by which the success may be proved. 1. Either a child must be forbidden communion with a church until vaccinated; 2. Or it must be forbidden registration; 3. Or it must be officially inspected at a given time after birth; 4. Or a public officer must be empowered to visit every child at some period, and, *vi et armis*, vaccinate it. Dr. Richardson contended that, in Great Britain and Ireland, not one of these methods could be carried out. This fact had been recognised by all our legislators; and, as a consequence, every legislative scheme became a half-and-half measure, sufficiently despotic to excite vehement opposition, and sufficiently inoperative to breed contempt. Dr. Richardson next analysed Mr. Bruce's Bill, and maintained that it had all the faults of previous measures. The registration scheme would fail, because there was and could be no such thing as enforced registration. The machinery for carrying out the purposes of the Act was loose and feeble; the law was left entirely permissive; there was no attempt made to secure revaccination; and the means were not afforded for giving the Registrar or other appointed officer the power to inspect. On the medical side of the question, Dr. Richardson urged that vaccination could only be carried out efficiently by and through the moral suasion and influence of the medical body as a whole. He held that the plan proposed by Dr. Lilley, for making every medical man a public vaccinator, and for paying small fee (say of 1s. 6d.) for every certificate of successful vaccination supplied to the registrar by the medical man, would be the most efficient plan that could be carried out. The payment of the certificate-fee would not interfere with the payment for the operation by the friends of the child; and it would be an inducement in every case to the practitioner to see every child under his care properly vaccinated. It was vain to say that every child, whose parents could not pay their own medical man, must perforce be vaccinated by another medical man. On this point of selection of the operator, the poor, not less than the rich, had deep feeling; and that feeling in both classes, in one as much as in the other, must be respected. It was a correct feeling, and an Englishman who ignored it would not be worth legislating for at all. The only argument worthy of notice against the principle of making every medical man a public vaccinator was, that under such a system the supply of fresh lymph could not be kept up. In reply to this, Dr. Richardson said that at present the supply from the vaccine stations was ineffective, and could never be regulated by law, inasmuch as the Act did not and could not give any vaccinator the right to take matter from the arm of any

child without the consent of the parent. On this topic he read a letter from Mr. H. Perry, jun., of Northampton, in which the same fact was brought out. He then passed on to explain that, if every man were a public vaccinator, there would be more vaccination; and that it could not be of moment whether one man vaccinated one hundred children on a given day, or whether a hundred men did it. Mr. Richardson summed up by suggesting the formation of a Central Vaccine Board which should collate all the facts respecting vaccination and small-pox throughout the country; which should receive the certificates of vaccination, and be a board of reference and general control. Such a board, supervising the whole kingdom, and having every qualified medical man who wished to become its officer, would be most efficient; it would secure by its moral influence a thorough vaccination of the whole kingdom; and the people would soon learn, without coercion, the great blessing bestowed on them, by the great practical good that would follow.

The PRESIDENT, after some remarks on the importance of the subject brought forward, observed that there had been a great reduction of liability to small-pox in this country since the introduction of vaccination; but still the rate of mortality from the disease was higher than in some parts of the Continent. With regard to the objection against compulsion, the misfortune was that, by leaving vaccination in the hands of the public, and through its consequent neglect, the enlightened portion suffered as well as the unenlightened. It would not be right to introduce despotic means of enforcing vaccination; but still it would be a pity if some measures were not taken. He agreed with Dr. Richardson that it would not be practicable to enforce vaccination through the Church. Nor could its universal performance be guaranteed by means of the registration of births; for a very large number of births—which he believed might be estimated at 500,000—were never reported. He feared that it would not be possible to make such new enactments as would thoroughly meet the demands of the case; but that much must be left to the march of intellect.

Mr. HUNT said that, ten or twelve years ago, he was a member of a Vaccination Committee of the Epidemiological Society. At that time Lord Lyttelton's Bill was under consideration, and the Committee waited on his lordship, and expressed their opinion that any plan for compulsory vaccination would never succeed. The result proved that this opinion was correct: the Act had been again and again altered, but an efficient system of public vaccination was as distant as ever. He agreed with Dr. Richardson that there was very little hope of success from compulsory vaccination; but, at the same time, it must be remembered that in many continental countries it has been successful. He (Mr. Hunt) had had occasion, as a member of the Committee he had mentioned, to examine returns on small-pox and vaccination sent from Bengal and Bombay. In Bengal vaccination could not be made general, on account of the religious prejudices of the natives, and hence there had been severe inroads of small-pox in Calcutta and other places. This evil state of matters extended over the whole of the Bengal presidency. In Bombay, on the other hand, compulsory vaccination was carried out most successfully; and small-pox was of extremely rare occurrence in the entire presidency, scarcely any cases occurring but such as were imported by strangers. These facts taught two lessons: first, that vaccination was capable of abolishing small-pox; and, second, that compulsory vaccination could not be carried out where political or religious prejudices prevailed. The great thing to be done was to enlighten the public—to show them that the occurrence of small-pox could be prevented by vaccination. As an illustration of the efficacy of thorough vaccination, he mentioned that, from 1812 to 1820, he had been in practice in a district extending over sixty or seventy square miles, and during that time he heard of only two cases of small-pox. There was no reason why, in like manner, small-pox should not

be abolished over the entire country. He felt strongly that, if the whole population could be vaccinated, the country would be free from small-pox; but the great difficulty was, how to effect this universal vaccination.

Dr. FRIZPATRICK had been in charge of large districts in the Madras presidency, where attempts had been made to enforce vaccination, but had been defeated by religious prejudices, the native vaccinators being mostly men of low caste. Subsequently, vaccination had been more extensively carried out, and the amount of small-pox was much diminished; but still the disease was very frequent. The natives endeavoured to escape vaccination; and would often, when vaccinators were sent among them, retreat into the jungle. There was this difficulty attending the attempt to carry out vaccination in Madras, that it was an object with the vaccinators to report as many successful cases as possible for the sake of the pay, but there was no guarantee that the operations had been properly performed. It had been found on examination, indeed, that many of the vaccinators did not understand their duty; and that many thousands of those reported to be successfully vaccinated were not safe against small-pox. Within the last few years, inspectors had been appointed, to examine the cases reported to have been vaccinated. With regard to bad vaccination, he would observe that, even in this country, the operation was not always properly performed; the vaccine matter, as he had seen in cases which had come under his notice while attached to the dispensary in Bath, was sometimes taken from diseased children. The main point in carrying out vaccination was to take care that the lymph was good; and he saw no reason why vaccination should not be made compulsory.

Dr. HILLIER differed greatly from the opinions expressed by Dr. Richardson. Much must, indeed, be done by educating the people—and this was a most important matter. But compulsory vaccination was not only possible, but advisable. He would not say that an absolute compulsory system could be carried out; but, in a modified form, it would be likely to prevent the omission of vaccination through pure negligence. It was for the children of parents who cared little about them, or who were constantly moving about, that an authoritative plan of vaccination was most required. In order that any plan of compulsory vaccination might be useful, it was indispensable that the vaccination should be efficiently performed, and that there should be a supply of good vaccine lymph; imperfect or careless vaccination, and the employment of bad and useless lymph, furnished a reason for opposition. In order to ensure a supply of good lymph, there should be a reduction of the number of vaccinators; they should be appointed by Government, and the vaccine stations should be placed under careful inspection. So long as a multiplicity of vaccinators was kept up, they must be necessarily driven to employ all kinds of expedients for obtaining good lymph, unless they could keep up the supply of vaccinated children. If public vaccinators were appointed in the way he proposed, it might be that the English feeling would prevent many persons from employing them; but he believed that ultimately even those persons who could pay for the operation would bring their children to them. Mr. Bruce's Bill was not altogether satisfactory as a means of enforcing vaccination; but it was an improvement on previous measures, as the onus of non-compliance would rest with the parents or guardians of the child. He saw no reason why the registration of births should not be made compulsory. There was a way in which vaccination might be encouraged: every child, before entering a national school, or being entitled to Government aid of any kind, should be required to present proof of vaccination; and the large employers of labour should be recommended to enforce a similar rule.

Dr. T. BALLARD expressed his want of belief in the occurrence of the disastrous consequences which were alleged to follow vaccination—except syphilis, the communication of which by vaccination was still *sub judice*, and

was certainly very rare. So long as medical men recognised such consequences, the public would believe in their occurrence. The symptoms which were alleged to follow vaccination, he believed, were not due to this; but the subject required investigation.

Mr. LILLEY (who was present as a visitor) said that the inefficiency of the Vaccination Act now in force had been made apparent to him by the increase of small-pox among adults in his practice. He attended a number of mechanics and persons in similar circumstances, whose children were not vaccinated because the parents would not take them to the public vaccinator. He would make the law even more compulsory in one respect, by imprisoning those who neglected to have their children vaccinated. But he believed that the best way of overcoming objections was to recognise every medical man as a public vaccinator; so that, after attending a case of labour, he might vaccinate the child and furnish the necessary certificate, the payment for which should not interfere with his private fee.

Mr. HENRY LEE objected to the principle that Government should be expected to pay for vaccination in cases where the parents themselves were able to pay their medical advisers. He believed that the great impediment to vaccination lay in the prejudices which prevailed among the people, especially in the midland districts. There was, without doubt, a notion extensively prevailing that various diseases were produced by vaccination; and, he believed, this notion was supported by the circumstance that many had died after so-called syphilitic inoculation. In England there was, beyond question, a great deal of careless vaccination; and even on the Continent the common use of the word "pustule" indicated a misconception, for the pustular stage was not that in which lymph should be taken from the arm. But that vaccination produced all the diseases attributed to it he did not admit. It probably caused the development of latent diseases already existing; and it should be impressed on the public that the symptoms occasionally following vaccination arose in this way, and not from actual introduction; and that it was probably better that they should thus appear than become developed, perhaps under more unfavourable circumstances, at a later period. Syphilis, he believed, might be introduced by vaccination; but the accident was of very rare occurrence. Mr. Lee concluded by stating his conviction that it was most important that medical men should thoroughly understand the subject of vaccination, and that the public should be taught to feel confidence in the operation.

Mr. WILLIAM MARTIN asked how far the Government encouraged vaccination among public *employés*, except in the army, navy, and police. It might with advantage be enforced in the Post-office and other public departments. He suggested that the best means of promoting vaccination would be the formation of an association for the purpose.

Dr. CORMACK said that the great diversity of opinion which had been expressed in the course of the debate upon some of the most vital questions connected with vaccination, showed that medical men ought to criticise very leniently recent legislation on this subject. If the members of such a meeting as the present were at variance upon the fundamental scientific principles, whence was Parliament to derive its guidance? But was the diversity of medical opinion, which had cropped out in the debate, justifiable? He thought that it was at least very difficult to explain. Innumerable facts, and a constantly cumulating medical experience, showed that when there was an universally enforced system of efficient vaccination in a district, a total or nearly total immunity from small-pox was secured to the inhabitants of that district. As this fact had been kept in view in all recent legislation upon vaccination—from Lord Lyttelton's Act to the Bill of Mr. Bruce now before the House of Commons—some praise at least was due to Parliament; and the results of recent legislation proved, likewise, that it had not been altogether valueless. The appointment of public vaccinators had diminished the

prevalence of small-pox, and had almost banished it from some districts in which, up to the passing of Lord Lyttelton's Act, it had existed as a chronic scourge. No doubt the Vaccination Acts were still very faulty; but this had not arisen from ignorance by those who prepared them of what was required, but from the prejudices to which they had to yield, and the obstructions which they had to try to smooth down but dared not remove. The debates in Parliament proved the correctness of this statement. If the meeting proposed to take any action in this matter, by petition or otherwise, he (Dr. Cormack) would suggest that it gave chief prominence to the two points upon which Dr. Hillier had so well insisted—that provision must be made for *efficient* vaccination, and that the practice must be *compulsorily enforced* to the utmost possible extent consistent with public opinion. He (Dr. Cormack) thought that, if all medical men were recognised and paid as public vaccinators, according to Dr. Richardson's plan, it would be impossible to obtain security for efficiency: first, there would be an immense difficulty in keeping up over the kingdom an abundant supply and distribution of good vaccine matter; and, second, thorough inspection of the vaccinators would be impracticable. Now, unless the lymph were good and always forthcoming when required, there could be no such thing as an efficient system of national vaccination; and it would be equally in vain to look for such a system unless there were a very thorough inspection of the vaccination of the people independent of local authority. Vaccination was in itself a simple affair; but, nevertheless, it had been shown that all medical men were not trustworthy vaccinators. To prevent the natural jealousy of public vaccinators which many private practitioners entertained, it might be necessary to debar public vaccinators from private practice, and to make their posts adequately remunerative by diminishing their number in large towns. This would facilitate vigilant inspection, without which no system could be trustworthy. The principle of compulsion was difficult to carry out, but in itself it was not unconstitutional. The law did not allow a man to set fire to his house, as, by so doing, he endangered his neighbour's house. Why, then, should it allow a man to abstain from vaccinating his children? Was it less constitutional to restrain individual liberty, with a view to prevent a general conflagration, than for the purpose of preventing a general pestilence? Surely not. The principle of compulsion was in theory perfectly sound; the difficulty was how to carry it largely into practice, in such a way as not to make it offensive. More might be done by indirect methods of compulsion than had yet been tried. All children before admission to public or private schools ought to show proof of having been properly vaccinated; and the same rule might be applied to all workers in factories and to all such like assemblages, just as it was carried out in the military and police services. The objections to vaccination were applicable only under certain exceptional circumstances, and in a few cases. The scanty credit which vaccination received in some quarters was chiefly due to the want of a system to apply it efficiently to the whole community. That was a great social truth, which physicians ought to proclaim whenever there was an opportunity. To attract public attention to controversial questions, and to matters of mere medical curiosity connected with the subject, was a course to be avoided. It was calculated to obscure truth.

Dr. DUPLEX said that, in France, there was a law that no child should be admitted into a school before having been vaccinated; and that this regulation proved very effective.

Dr. STEWART said that the subject was one of increasing public importance. He differed to some extent from the views expressed by Dr. Richardson; and was strongly impressed with the importance of making vaccination in some sense compulsory. To hold out inducements might be a useful means of promoting vaccination; but that there was an effectual method was evident from a fact with which he had been much struck—that over nearly the whole of

Northern Europe small-pox might be said to be extinct. The English Government had already partially adopted the Continental system, by requiring that the men in the public services should be vaccinated; and he saw no reason why this experiment should not be carried out to a much greater extent. At present, instead of diminishing, the mortality from small-pox in this country was increasing. The prejudices which existed against vaccination in many parts of the country were greater than was commonly known. Mr. Lee had referred to the midland counties; and he (Dr. Stewart) had been repeatedly informed by his pupils of the prejudices which prevailed in the south-western counties—Devonshire and Cornwall. He had been informed that, in a town in the former county, there had been repeated epidemics of variola arising from inoculation, to which the inhabitants were accustomed to have recourse when there was any fear of small-pox. More recently, however, the prejudice against vaccination had been diminishing, principally in consequence of the action of the medical officers and public vaccinators. This fact showed that, by dealing with the people in the right way, their prejudices would be overcome. He agreed with the observation already made, that there were a large number of cases of imperfect vaccination; and he had found repeated evidences of this on inspecting the arms of his patients. Much of this imperfect vaccination, he believed, arose from the difficulty which private practitioners experienced in keeping up a supply of lymph. With regard to the proposed plan of appointing public vaccinators, he thought that it would be attended with much difficulty in country districts, where either the children must, with difficulty and perhaps with danger to their lives, be brought to the vaccinator, or the vaccinator must be paid large fees in consideration of the distances over which he had to travel. In large and populous centres, on the other hand, this difficulty did not exist; and in these the appointment of public vaccinators would be advantageous.

Dr. RICHARDSON had been much interested by the discussion, and hoped that the subject would not be dropped, but that the Branch would again meet and take some action in the matter. Even in the present meeting all phases of public opinion were represented; some of the members being in favour of compulsory vaccination, while others were opposed to it. Seeing that there was such difference of opinion among medical men, it was right that, as Dr. Cormack had suggested, the public should be treated leniently. The discussion had only strengthened his conviction of the impossibility of enforcing vaccination. There was a way of endeavouring to gain an object by always catching at it without success. This was the way in which it had been attempted to carry out vaccination; and to it he attributed the retrograde movement which had taken place in this direction. It was impossible to make vaccination compulsory; and the attempt only brought discredit on the proceeding. How could compulsory regulations be effective in the face of prejudices? Again, compulsory vaccination was opposed to the common law. He repeated, that Mr. Bruce's Bill showed the futility of attempts to enforce vaccination. The bill was permissive in some most important parts; the twenty-ninth clause was of this character. The clause spoke of a "Registrar, or any officer appointed by the Guardians to enforce the provisions of this Act." Was it certain that the Guardians would appoint such an officer? Again, if such officer "had reason to believe that any child under the age of 13 years had not been vaccinated, etc." How was he to prove the grounds of his belief? He had no power to do so. What, too, was to be done in the case of non-vaccinated persons above the age of 13? The clause further provided that the Justice receiving the information may summon before him the person having the custody of the child, and make an order for vaccination. Would this provision be carried out by the Justices? The neglect of the order rendered the offender liable to a penalty not exceeding twenty shillings. Was this likely to be a sufficient

penalty? Again, the bill was defective, inasmuch as it made no provision for revaccination, nor for the vaccination of unregistered persons. Gipsies, for instance, did not have their children registered, and were constantly moving from place to place; and he (Dr. Richardson) had known an epidemic of small-pox to have been introduced by them. It would be better to have no Act at all than one of which the provisions could be so extensively evaded. With regard to the enforcement of vaccination on children before being admitted to schools, he did not see how it could be carried out; as a matter of feeling he did not think that the proceeding would be a right one. To imprison persons for not having their children vaccinated would do more than anything else to establish prejudices against vaccination. The plan of having independent vaccinators, proposed by Dr. Cormack, would lead to great expense. Supposing that only one vaccinator were appointed for every four union medical officers, an outlay of £72,000, not including travelling expenses, would be required. The plan would, he believed, be impracticable. The effect of the plan proposed by Dr. Lilley would be, that every medical man would feel an interest in vaccination, as it would be productive of addition to his income. It was objected that under this plan it would be difficult to keep up a supply of lymph; but in answer to this he would observe, that the same difficulty was met with at present in obtaining lymph from the central stations, and that, if the vaccination were efficiently carried out, the supply must be the same, whether there be one vaccinator or twenty thousand.

#### THE LONDON COLLEGE FELLOWSHIP.

DURING the last few days the usual half-yearly examination of members for the Fellowship of the College has taken place; it is stated that there were six senior candidates, and only four juniors. The following were the questions on anatomy and physiology submitted on this occasion to both seniors and juniors—viz.:

1. Describe the head and neck of the femur, and the trochanter major in the child. What are the bloodvessels and nerves which supply them? and enumerate the changes which take place in these parts until old age.
2. Describe the various means by which the urinary organs and their appendages are maintained in their position, and all the differences which exist between them in a male child and in an adult.
3. Describe accurately the course of the tendons at the inner and outer ankle and in the sole of the foot, their insertions and relations, and all the functions these tendons perform.
4. Give an account of the structure of the spinal cord. Enumerate the experiments which have been performed with the view of ascertaining its functions.
5. Describe the minute structure of the skin and its appendages, and the functions they perform.
6. By what means is the heat of the animal body produced, regulated, and maintained?

The following are the questions on surgery and pathology,—viz.:

1. Describe the causes, the symptoms, and the progress of acute inflammation and necrosis of the femur, the several means adopted by nature to effect a cure, and the surgical aid you would employ.
2. Describe the various fractures which may occur to the neck of the femur, the trochanter major, and the acetabulum, with the symptoms and the appropriate treatment in each case.
3. How are fractures of the base of the cranium caused? What symptoms usually accompany these injuries? What effects may they produce on the brain and cerebral nerves? What treatment would you adopt?
4. Under what circumstances would you consider it advisable to perform the operation of ovariectomy? Describe what would be the best manner of proceeding, the means by which you would secure the bleeding vessels, the difficulties and the dangers which attend this operation, the after-treatment, and the proportion of cases which prove fatal.
5. Under what circumstances is it necessary to remove the

astragalus? Describe the difficulties which attend this operation, and the probable results.

6. Describe the various diseases of the iris and the accidents to which it is subject, the effects they produce, and the constitutional and surgical treatment you would employ for their cure or relief.

### Medical Obituary Notices.

WILLIAM DAWSON, M.D.,  
NEWCASTLE-ON-TYNE.

DR. DAWSON was a native of Newcastle-on-Tyne, and was born in the year 1805. He served his apprenticeship to Mr. Thomas Elliott, a gentleman who conducted an extensive general practice at the time in Newcastle, and who was afterwards founder of the lying-in hospital there. He passed his examination at the College and the Hall at an early age, and commenced practice in a very populous district in his own town. Being a man of remarkable energy, fond of the work of his profession for its sake, he soon acquired a very extensive obstetric practice—not a lucrative one by any means, as he often himself remarked, but still valuable to him or to any man like him who could profit by the opportunity it afforded of displaying great natural abilities, and as yielding a rich mine of experience, to be turned to account at a future day. Year after year he toiled on, and at one period of his career it was doubtful if any of his competitors had attended half so many midwifery cases; but there was another thing which admitted of no doubt—namely, that there was no man who had attended so many cases, or worked so hard, for so little remuneration. In the year 1846 he received his degree of M.D. from St. Andrews, and removing to a more commodious residence, and a better locality in the town, his practice as a consulting accoucheur increased rapidly; and, indeed, few difficult cases occurred in the town or surrounding counties without his advice or aid being sought. Nor was his fame in his own department confined solely to the north, for of late years he was accustomed to make very long professional journeys; and only a few weeks ago a lady came from China to place herself under his care. As a practitioner he was ready in diagnosis, his immense experience enabling him to apprehend the leading points of a case as if by instinct; fertile in resources as a prescriber, rarely giving a patient up, trying means after means, infusing by his manner, and, as it were, by his very presence, confidence and hope. By his natural gifts he was well adapted for the position which he occupied, and he achieved an amount of success rarely attained by a provincial practitioner—a success legitimate and well deserved, because it was founded upon years of hard work and rectitude of conduct. He was a lecturer on midwifery for many years, and held the office of physician accoucheur to the Lying-in Hospital, and was likewise President of the North of England Obstetrical Society, in the foundation and progress of which he took a very great interest. As a teacher he was clear, forcible, and practical, quoting case after case, and leaving his pupils in no doubt as what was best to be done; others might, perhaps, talk and theorize with more effect, whilst he possessed the art, and to see him perform some difficult obstetric operation was to receive a lesson of value never to be forgotten.

For some time past it was apparent to his friends that he was not in his usual state of health. About two years ago his only son, a surgeon, died; and soon after this he sustained an injury to his leg in a railway collision. These circumstances made an evident inroad on his constitution. On the 7th of May he went up to London for a little relaxation, and on the 15th he felt unwell. Next day he was suddenly seized with erysipelas of the face, followed by great tumefaction and cerebral symptoms. These continued to increase, and exhaustion soon setting in, he died on Sunday, May 20th, in the sixty-first year of his age.

He was attended by Dr. Leared, Mr. Wetherfield, and his townsman, Dr. Embleton. His remains were removed

## Medical News.

to his native town, where they were followed to the last resting-place by most of the profession, the students of the Medical College, old friends, and patients, and many brethren as mourners from long distances. Kind-hearted, unselfish, and generous almost to a fault, a life like his gone from amongst us leaves a blank impossible to fill up; for of the many losses the profession in Newcastle has sustained by death of late, no one has been so generally missed, so universally esteemed and regretted, as Dr. William Dawson.

### SAMUEL SMITH, Esq., M.R.C.S.

ON the 15th of April, at his residence at Ardres, in the Pas-de-Calais, after a short illness, died, in his ninety-second year, Mr. Samuel Smith, one of the oldest members, if not the oldest member, of the Royal College of Surgeons of England, he having been a member upwards of seventy-two years. He was son of Samuel Smith, Esq. (*ex officio*), of Kilburn, Middlesex, and Shute, Devon, whose ancestors were freeholders in Devon and Cornwall before the Reformation. As affording an illustration of hereditary longevity, it may be stated that for the last 250 years several among the ancestors of Mr. Smith, who himself lived during six generations in the direct ascending and descending lines, had lived to see the fourth generation in descent from themselves. Mr. Smith was born on the 8th of September, 1774, at St. Martin's-le-Grand, London, received his general education at the public grammar school, Lostwithiel, and was apprenticed in May, 1787, to his first cousin, Dr. Davis, of Fowey. He afterwards studied at the University of Cambridge, attending the anatomical lectures of Sir Busick Harwood. Being desirous of entering the public service, he passed, in the year 1793, an examination before the Society of Apothecaries, a body which in those days examined in pharmacy, and was recommended by the Hall to the Admiralty, Somerset House, for an appointment at the Naval Hospital, Haslar, where he was appointed visiting apothecary under Dr. Lind, many of whose clinical notes are in Mr. Smith's handwriting. Here, in 1793, he was nearly carried off by an attack of fever, caught while attending the crew of the Portuguese fleet. After his recovery, wishing to leave the medical for the surgical practice of the hospital, he presented himself, when nineteen years of age, before the Corporation of Surgeons of London, and passed his examination (as shown by the manuscript list preserved in the College) on the 2nd of January, 1794, although his diploma is dated the 17th of April, 1800, when he commenced practice in London. Mr. Smith was deputed by the naval authorities to take the sole surgical charge at Forton of the French prisoners brought in by Lord Howe's fleet after the battle of June 1st, 1794. He continued in the naval service at Haslar until he joined as surgeon the Northumberland Fencibles, a regiment raised by Sir Francis Drake for suppressing the Irish rebellion of 1798. In April, 1800 (as before stated), Mr. Smith commenced private practice as successor to Mr. Farley, of Holborn-bars. Thence he removed to Bedford-row, and since his retirement, upwards of forty years ago, he has chiefly resided in the north of France. He was twice married, and has left several sons, all of whom are members of his own profession.—*Lancet*.

### MEDICINAL VIRTUES OF EXTRACTUM JALAPÆ.

In answer to the query published by the American Pharm. Assoc.:—"Does the aqueous extract, prepared from jalap that has been previously extracted by alcohol, possess any medicinal properties; or does the alcoholic extract of jalap fully represent its virtues?" Mr. A. B. Taylor states that he prepared an extract, and subjected it to experiment. He took 30 grs. at 10 a.m.; at 12 a.m. no action having been produced, he repeated the dose. This dose was repeated every hour until eight doses were taken—no apparent effect being produced from a total dose of 240 grains.

From this experiment it would appear that "Extractum Jalapæ," U.S.P., is an unscientific preparation.—*Year-Book of Pharmacy*.

ROYAL COLLEGE OF SURGEONS, IRELAND.—The following gentlemen passed the first half-examination, May 9th:—

|                        |                    |
|------------------------|--------------------|
| Mark Anthony,          | Charles McCarty,   |
| Frederick Barka,       | William McManis,   |
| Joseph C. Barker,      | Richard Moran,     |
| John O. Blunden,       | Alfred O'Connor,   |
| Anthony L. Brown,      | Donald O'Connell,  |
| Penwick Carr,          | Thomas O'Reilly,   |
| James B. Draw,         | Richard Parks,     |
| Joseph H. Fitzhugh II, | George P. Stokes,  |
| Thomas J. P. Holmes,   | Henry G. Thompson, |
| Bernard O. C. Keelan,  | Charles Woolworth. |
| W. McConaghy,          |                    |

The following gentlemen passed the final examination, May 16th:—

|                      |                  |
|----------------------|------------------|
| John O. Blunden,     | Richard Moran,   |
| Thomas J. P. Holmes, | Thomas O'Reilly. |
| Hickman Morgan,      |                  |

DR. RICHARD CROSS has been appointed one of her Majesty's Justices of the Peace for Scarborough.

REPORTS addressed to the Italian Minister of War state that fever has broken out among the troops at Florence, and typhus is feared.

MR. J. BOCKETT has just pointed out a serious defect in the "double objective holder" now used by microscopists. It consists in the want of correspondence between the optical centres of any two object-glasses. Mr. Bockett has contrived an ingenious apparatus for obviating the error.

ONE thousand and fifty-seven dogs were drowned in Belfast during the last month. This is the report of the sanitary inspector, who appears to have more trouble with dead dogs than with his legitimate duty. The hauling of these dogs out of the water and their interment cost £2 7s. 6d.—*Northern Whig*.

HEARTRENDING accounts continue to be received of the famine in Orissa, India; it is even said that cases of cannibalism have occurred.

AUTHENTIC advices received at Alexandria from Djeddah report that cholera has broken out among the returning pilgrims from Mecca, and that there is great mortality among the Egyptian soldiers.

THE CATTLE PLAGUE IN IRELAND.—The Mansion House Cattle Plague Committee met one day last week at the Mansion House, Dublin, when resolutions were passed requesting the Government to have reports published in the newspapers, and also than an experienced non-professional man be associated with a veterinary surgeon in each case of reported rinderpest.

ON Saturday week, the usual dinner of the Royal College of Surgeons of Ireland took place at Bray, and was attended by some of the leading medical men of Dublin. The dinner was given by the Council of the College to the President, Mr. Willmott; Dr. Butcher occupying the chair, and Dr. J. S. Hughes the vice-chair.

IN the week just ended the births in London were 1919, and the deaths, 1467.

A GERMAN physician is publishing a series of letters in the *Augsburg Gazette*, affirming that there exist at the present moment in Germany such germs of disease, that if war should break out, it would inevitably lead, in consequence of the conglomeration of large masses of men, to the most terrible epidemic of cholera ever witnessed.

THE EDINBURGH MEDICO-CHIRURGICAL SOCIETY held the tenth meeting of the forty fifth session in their hall, 117, George-street, on Wednesday, the 6th inst., at eight o'clock, p.m.—Dr. Moir in the chair. Dr. J. D. Gillespie read a "Case of Removal of a Fibrous Tumour of the Uterus, weighing twenty-nine pounds," and Dr. Warburton Regbie read a case of "Addison's Disease," observed and related by Dr. Whiteford, Greenock.

THERE is such a dearth of physicians and surgeons in the Austrian navy that the Government offers to engage young men who have not yet completed their medical studies.

MR. WILLIAM MACGILL has bequeathed to the Edinburgh Royal Infirmary a property of the present value of

£10 000. Mr. Macgill directs that the property shall not be sold, but retained by the incorporation, and the rents applied to the purposes of the calamity.

The *Brighton Guardian* records the death of a man in that town from eating a large quantity of mussels.

A CASE of anthropophagy has been before the French tribunals last week. A young girl, of eleven years of age, attempted successively the life of her mother and sister for the purpose of drinking their blood. Her extaeme youth leads the physicians to hope that her cure may be accomplished.

## Notices to Correspondents.

*Another Victim of Quackery, Eilingburgh.*—The gentleman named has had considerable experience in the treatment of the complaint alluded to. *W. C. T.*—The communication has been received.

*A. B.*—The subject shall receive our early attention.

*Amicus.*—We believe the strictures to be just, and therefore we do not feel disposed to take up the cudgels in defence of the persons alluded to.

*Dr. T.*—According to the version of the affair laid before us, it does not appear that our correspondent has committed any breach of professional etiquette.

*The Royal Institution of Great Britain.*—The notice has been received.

*A Student.*—The particulars will be found in our Reports of the Proceedings of the Medical Council.

*Mr. H.* informs us that there are certain unqualified persons in his vicinity, who, being unable to practise legally, procure the services of qualified members of the profession and, with the latter, visit patients. Our correspondent indignantly asks how it is that duly qualified practitioners can condescend to such a questionable mode of making money?

*Mr. Griffin, Weymouth.*—The paper on Poor-law Medical Reform has been received.

## Vacancies.

Braintree Union (Parish of Finchingfield)—Medical Officer.  
Brighton and Hove Dispensary—Resident Medical Officer and Dispenser for the Western Branch.  
Dartford Union Workhouse—Medical Officer.  
Denbighshire Infirmary—House-Surgeon.  
House of Correction, Northallerton—Surgeon.  
Kent and Canterbury Hospital—Assistant House-Surgeon.  
Birkenhead—Medical Officer of Health.  
Salford and Pendleton Royal Hospital and Dispensary—Two District Surgeons.

## Appointments.

R. J. CANE, L.R.C.S.I., L.M.R.C.S., Resident Surgeon to the Birmingham Lying-in Hospital and Midland Counties Dispensary for the Diseases of Women and Children, has been elected a Fellow of the London Obstetrical Society.  
F. CLARKE, M.B., F.R.C.S.I., has been appointed Surgeon to the Constabulary, and Surgeon and Agent to the Coast-Guard, Dunfanaghy, Co. Donegal, vice R. H. Macglothin, M.B., C.M. Dub., appointed Medical Officer for the Terryglass Dispensary District, Borriskane Union.  
F. W. CLARKE, M.R.C.S., L.S.A., has been appointed Medical Officer to District No. 2 of the Oxford Lying-in Charity.  
G. CLEMENTS, M.R.C.S.E., late Senior House-Surgeon to the Manchester Royal Infirmary, has been appointed Resident Medical Officer to the Salford Union.  
E. ELLIS, M.D., has been appointed a Physician for Out-Patients to the Samaritan Free Hospital for Women and Children.  
A. EYTON, L.R.C.P. Ed., has been appointed Medical Officer for District No. 4 of the Wrexham Union, Denbighshire, vice J. F. Churchill, L.R.C.P.L., resigned.  
M. W. FISHER, L.K.Q.C.P.I., has been appointed Medical Officer to the Constabulary, Mountrath, Queen's County, vice F. Clarke, M.B., resigned, on being appointed Medical Officer to the Dunfanaghy Dispensary District and the Workhouse of the Dunfanaghy Union.  
Mr. R. HUDSON, Surgeon Royal West Indian Mail Service, has been elected a Fellow of the Anthropological Society. Mr. Hudson has also been elected a Fellow of the Royal Geographical Society.  
R. N. INGLE, M.D., of Pendleton, has been elected Visiting Surgeon to the Salford Workhouse, vice M. O. Larmuth, M.R.C.S., deceased.  
J. R. KEALY, M.D., M.R.C.S.E., has been appointed Surgeon to the Portsmouth, Portsea, and Gosport Hospital.  
J. MURRAY, M.B., M.R.C.S., has been elected one of the Resident Clinical Assistants to the Middlesex Hospital.  
C. ORTON, L.R.C.P., Ed. (late House-Surgeon to the Infirmary) has been appointed one of the Honorary Medical Officers to the North Staffordshire Infirmary.  
J. J. PHILLIPS, M.B., has been appointed Demonstrator of Anatomy at Guy's Hospital.  
W. H. PLATT, L.R.C.P. Ed., has been appointed House-Surgeon and Secretary to the Scarborough Dispensary, vice F. M. Fawcett, M.R.C.S.E., resigned.  
M. K. ROBINSON, M.R.C.S.E., Medical Officer of Health for Birkenhead, has been appointed Sanitary Inspector for the Borough of Leeds.  
P. H. PYE-SMITH, M.D., has been appointed Demonstrator of Anatomy at Guy's Hospital.  
H. B. SPENCER, M.D., M.R.C.S., has been appointed Medical Officer to District No. 1 of the Oxford Lying-in Charity.

## Medical Diary of the Week.

LONDON—WEDNESDAY, JUNE 13.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Professor Hancock, "On the Anatomy and Surgery of the Foot."  
MICROSCOPICAL SOCIETY OF LONDON.—8 p.m. Mr. R. Beck, "On the Function of some peculiar Vibrating Hairs on Spiders and Insects."

FRIDAY, JUNE 15.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Professor Hancock, "On the Anatomy and Surgery of the Foot."

ROYAL INSTITUTION.—8 p.m. Prof. Tyndall: "Experiments on the Vibrations of Strings."

WED. Geological, 8.—"Metamorphic and Fossiliferous Rocks, County Galway," Professor Harkness; "Metamorphic Rocks, Carrick, Ayrshire," Mr. Geikie; "Chirotherian Footprints from the Keuper," Professor Williamson; "Heaves or Trocs in Penhall Mine," Mr. Pike.

— Literature, 8½.—"Monasteries of Mount Athos," Rev. J. Beaumont; "Expedition to Palestine," Mr. Vaux; "Coins of Crete," "Stylograph of the Crucifixion," Mr. Hogg.

THURS. Royal Institution, 3.—"Ethnology," Professor Huxley.

— Royal, 4.—Election of Fellows.

— Chemical, 8.—"Course of Chemical Action," Mr. Harcourt.

— Linnean, 8.—"Myostoma," Mr. Miers; "Cortical Cuneate Rays," Dr. Sigerson; "New Zealand Lichens," Dr. Lindsay; "Surface-Fauna of Mid-Ocean," Major Owen.

— Antiquaries, 8½.—Election of Fellows.

FRI. Royal Institution, 8.—"Muscular Power," Professor Frankland.

SAT. Royal Institution, 8.—"Ethnology," Professor Huxley.

— Botanic, 3½.

## WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING JUNE 9TH, 1866

By J. H. STEWARD, Strand, and Cornhill, London.

| June, 1866. | Barometer reading reduced to 32 degrees. | Thermometer. |       | Dry bulb. | Wet bulb. | Wind.      |        | Rain. | Remarks.   |
|-------------|------------------------------------------|--------------|-------|-----------|-----------|------------|--------|-------|------------|

## Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

ALLINGHAM. On June 5th, at 36, Finsbury-square, the wife of W. Allingham, Esq., Surgeon, of a son.  
ARNISON. On June 1st, at Allandale Town, Northumberland, the wife of George Arnison, Esq., Surgeon, of a daughter.  
BOWER. On May 28th, at Windsor, the wife of E. Bower, M.D., of a daughter.  
KINGSFORD. On June 1st, at Upper Clapton, the wife of Charles D. Kingsford, M.D., of a daughter.  
LYSTER. On June 3rd, at 8, Devonshire-road, Prince's Park, Liverpool, the wife of C. E. Lyster, Esq., M.D., of a daughter.  
TANNER. On May 31st, at Henrietta-street, Cavendish-square, the wife of Thomas H. Tanner, M.D., of a daughter.  
TERRY. On May 28th, at Newport Pagnell, the wife of Charles Terry, Esq., of a son.

### MARRIAGES.

BELCHER, William Douglas, Esq., of Kennington, to Edith Anna, daughter of William M. Boase, M.D., of Plymouth, at Kennington, on May 4.  
CROWTHER, Edward, Esq., second son of Baker Crowther, Esq., Moor Allerton, Leeds, to Eliza Anne, eldest daughter of John Skevington, Esq., of Ashbourn, on June 6.  
DAVIS, Major Gronow, V.C., Royal Artillery, to Anna Wilhelmina Mary, fourth daughter of H. Cooper Reade, Esq., Surgeon-Major, at Clifton, on May 30.  
EASTCOTT, James C., Esq., Surgeon R.N., to Emily Catharine, only surviving daughter of William Roberts, Esq., H.M. Inland Revenue, London, on June 2.  
FORSALL, Francis H., Esq., L.R.C.P., of Highgate, to Frances Maria, eldest daughter of W. W. Scringueur, Esq., of Highgate, on May 31.  
PROBERT, James, Esq., Plymouth Ironworks, Merthyr Tydfil, to Anne, youngest daughter of the late Thomas Morgan, Esq., of the Graig, Merthyr Tydfil, at Bedwas, on May 29.  
TUCK, William H., Esq., eldest son of the Rev. W. G. Tuck, M.A., of Tostock House, Suffolk, to Jane St. John, only daughter of John Wreford Budd, M.D., of Plymouth, on May 29.

### DEATHS.

ANDERTON. On May 20th, at Wavertree, near Liverpool, aged 72' Mary Elizabeth, wife of Henry Anderton, M.R.C.P. Ed.  
COLLET. On May 27th, at Worthing, aged 18, William Edmond, second son of Henry James Collet, M.D.  
HAYNES, Raymond Levi, Esq., Surgeon, at Haringey Park, Crouch End, Hornsey, aged 57, on May 31.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

Original Communications.

ON MIXED TYPES OF FEVER;  
IN RELATION TO THE QUESTION OF THE  
IDENTITY OR NON-IDENTITY OF THE  
TYPHUS AND TYPHOID POISONS.

By HENRY KENNEDY, A.B., M.B.,

FELLOW AND CENSOR OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS, ATTACHED TO SIR P. DUN'S HOSPITAL, AND ONE OF THE PHYSICIANS OF THE CORK-STREET HOSPITAL.

(Read before the Association of the College, 9th May, 1866.)

OFTEN as the subject of fever has been brought before the Association, there still remain a number of points to be cleared up. Few of them, however, have attracted a more general attention than the one to which I ask your notice this evening. It is the question of the identity or non-identity of the two types of fever known as typhus and typhoid; in other words, will the one poison produce the two types? or are they due to separate and distinct poisons? In England, Ireland, and Scotland, as well as on the Continent, and in America, these questions have been written about again and again, and yet the matter is not settled. It is quite true the London physicians speak of it as if it were, and I have been credibly informed that any student going before them for examination, and not answering according to their views, will be rejected. This, I must say, is going rather too far with the matter. Not that for a moment I question the truthfulness of what they have stated, and more particularly what has been advanced in such an elaborate way by Dr. Jenner, but that I have the strongest convictions they have not seen fever on so large a scale as others, and have not given that consideration to the statements of others to which they were fairly entitled. I have been always at a loss to understand why the work of Huss has been so utterly ignored. He saw fevers on a very large scale, and his work is written in a calm and dispassionate spirit, and yet not an attempt has been made, as far as I know, to answer his arguments or overturn his facts. Surely, in such a widespread disease as fever, no one is justified in asserting that what they have seen is what must have been seen by others. We know that even in the type of fever familiar to us as typhus, very great differences exist, and may be constantly seen when the disease attacks several members of the same family. In one, the head symptoms are all in the ascendant; in a second, the chest will be the part attacked; whilst in a third, it will be the stomach in the form known as gastric fever. Or, again, as regards the spots, the husband will present them and the wife not, or the parents will have them and the children not; or it may be the converse of this. In a family named Bright, of whom eight were in hospital at the same time, and who were sent in by Dr. Carte of the Royal Hospital, the children were all spotted, whilst the mother had none, though she had a very severe attack of fever. Again, in three sisters, all adults, who were recently in hospital, only one had the regular spots of the disease; in the other two anything of rash was most indistinct; one of these latter died. Further still, in the great epidemic of 1847-48, the fever was what is known, and had been described previously, as the relapsing fever; that is, it was made up of two parts. There was a sharp attack of fever running on for five or seven days; then a lull of one, two, or three days; and

again an onset of fever, usually much severer than the first, and, in very many cases, attended by spots. No one, I think, could have any doubt but that it was one and the same poison which caused the two attacks; and yet, in all the recent and standard works on fever, the relapsing type is described as if it were a totally different fever from typhus, and caused by a different poison. I cannot give in my adhesion to this opinion, for I have as strong a conviction as the nature of the subject admits that the poison of typhus generates not only the type of fever known as relapsing, but other types, such as nervous, gastric, cerebral, &c., as also fever, both without and with spots, and presenting all the variety which they are capable of exhibiting; and if this view of the typhus poison be not held, insuperable difficulties, as it appears to me, must arise when we come to consider analogous diseases to fever, as, for instance, scarlatina. Here every one must have seen the great variety—I might almost say contrasts—which this disease often presents in the same family and at the same time. Yet no one ever thought of setting down these differences to different poisons; and why it should be necessary as regards fever it is not easy to understand. I must leave this point to others to settle.

From the tenor of these remarks it will be understood what are the views I hold on the question more immediately under discussion. I believe that the typhus poison is capable of engendering the type of fever known as typhoid or enteric, and that this particular type must be due to some other cause rather than a specific poison. On the other hand, I hold that the two types can, in the great majority of instances, be distinguished, the one from the other. When I brought the subject first before the Royal Medico-Chirurgical Society of London, in 1860, one of my arguments consisted in the detail of a few cases which were directly opposed to the views of the London physicians. In a later paper, published in the *Dublin Quarterly Journal*, a still larger number of cases were given, and I cannot, I believe, do better now than by giving the briefest sketch of some which have come under my notice within the last two years. But, in truth, I may say the difficulty now consists in selecting the cases, they have become so numerous. So I shall take such as bear most directly on the disputed point.

Case 1.—McKown, aged 17, having a fine skin, passed through a very severe attack of enteric fever. Every symptom was present, and during its progress the brain was much engaged, and the tongue and lips covered with sordes. He made a good though slow recovery.

Case 2.—His brother, æt. 12, from same room, was admitted under a severe attack of typhus. He had the well-marked and copious rash of the disease, and his face was quite characteristic. He had a sharp attack of diarrhœa, calling for a special treatment. My friend, Dr. Hudson, was kind enough to come and confirm my diagnosis of this case. It is but right to state there was an interval of a week between the admission of these two brothers.

These two cases have been given as affording an example of the two types of fever, each well marked, coming from the same room. Others, I know, have met similar examples, and Dr. Croly of Harecourt-street, has informed me of a very striking one.\*

Case 3.—McCauley, æt. 18, fine skin, was handed over to my care by my friend Dr. Moore. The patient laboured under fever, and had the spots of the enteric type very well marked on abdomen and sides of thorax, but there was no other sign whatever of this kind of fever. His illness ran on for many days, the chest becoming engaged, and when he left hospital there were signs about him as if phthisis might supervene.

Cases 4 and 5 were of a similar character to the one just given—that is, with fever, the spots were those of the enteric type, but no other symptom of that kind of fever.

\* After the reading of the paper Dr. Croly detailed three cases of fever which occurred in the one room. The first was a case of enteric fever, the second a case of typhus, whilst the third was a mixture of the two types.

As they were published, however, in the *Lancet* for December, 1864, I shall say nothing more of them here.

Case 6.—Podesta, an Italian, 14 years of age, and of a very fine skin, admitted into hospital in September, 1865. In the course of his fever he presented a very good example of the spots said to mark enteric fever. They were few in number, and appeared on the sides of the chest and abdomen. Neither in this case was there any other sign whatever of the enteric type of the disease.

Case 7.—Develin, a young man of 17, admitted into hospital during the present month, April, 1866. He had fever, but not of a severe kind, marked by the usual symptoms, and the tongue red and furred. When he was now six days ill the spots of enteric fever appeared on chest and abdomen, and in an unusually well-marked form. On the second day of their appearance this patient was seen by the Drs. Martin, from Berlin, who happened to be visiting the hospital. On the third day, however, the number of spots had greatly increased, and become more those of typhus, and finally the case, beginning with the spots of enteric fever, became one of regular typhus.\*

Case 8.—Keegan, a man of 27, admitted March, 1865. He was labouring under heavy spotted fever. Some of the spots were large and dark, some were unusually well defined and red, and disappeared on pressure. The case, however, was one of regular typhus, and the man made a good recovery.

Case 9.—Murphy, girl of 19, whilst passing through a severe attack of fever, with typhus spots, got a very sharp attack of diarrhœa, attended by tympany, and pain on pressing the ilio-cœcal region. Nothing checked this diarrhœa till special treatment was adopted.

Case 10.—A dumb girl, æt. 24, sent into hospital from the South Union. She had bad fever, being all covered with a copious mealy rash, whilst the tongue, face, and eyes were those which mark typhus. In the progress of the attack she got severe diarrhœa, attended by tympany, and distinct pain when pressure was made on ilio-cœcal region, and only here. This complication required specific treatment, and she got steadily but slowly well.

Case 11.—Dixon, man of 25, of a very fine skin, and thin, admitted into the Cork-street Hospital, labouring under fever, and with a copious rash of typhus spots over him. His general aspect that of the same type of fever. As the disease went on he got severe diarrhœa, the discharges being a light yellow colour, and attended by distinct pain in right iliac region, and tympany. This man also required specific treatment, and the attack was one of unusual severity, marked by great distress and restlessness. His recovery, too, was much prolonged by the occurrence of several abscesses.

Case 12.—In February, 1865, Kelly, a man of 19, was admitted into hospital. He was evidently very ill; but the symptoms of typhus and enteric fever were so mixed up that I was quite unable to say to which type of the disease the case ought to be referred. He had a copious rash over the body, and his expression was that of a man in typhus. But he had also slight though marked tympany, distinct pain on pressure over the ilio-cœcal region, and a very severe diarrhœa, the discharges being of a light yellow colour. He made a very slow recovery. *This man's sister was in hospital at the same time. She had typhus.*

Case 13.—Woods, a man of 20, came in with a kind of spurious fever on him. He then went out for some days, but returned in a week with every sign of enteric fever on him except the rash. He had, however, spots on him, which to my surprise turned out to be variola in the discrete form. Whilst still bed from this he seemed one day to get suddenly worse, and then typhus in a very severe form declared itself. During all this time he had sharp diarrhœa, and the discharges were those which I believe to be most characteristic of enteric fever, being of a light yellow colour. This patient's life was in the balance for many days, but he finally recovered.

\* It was observed that as the typhus rash declined the typhoid spots became again quite visible, and at this period a slight attack of diarrhœa occurred.

Case 14.—Barn, a girl of 16, admitted in July, 1865. She then laboured under a severe attack of typhus, being well spotted. She was so far advanced as to be sent to the Convalescent House, when she again sickened, complaining of her head, and this again followed by great raving and high fever. When now a week ill, the spots of enteric fever made their appearance. These were unusually well marked, being few in number, and confined to the sides of the chest and abdomen; but there was no other symptom whatever of enteric fever, and they were looked for, I need scarcely say, with the greatest minuteness, nor did any such appear. At this stage of her illness the patient was seen by Dr. Murchison of London, who was visiting Dublin at the time, but who, I regret to say, I was not fortunate enough to meet.

Such is the series of cases which I wish to bring under the notice of the Association this evening. When added to those already given in the two former papers—and, did time permit, I could have given other similar cases—they appear to me to afford the strongest proof the question is capable of eliciting, that we must consider the two types of fever known as typhus and enteric as the result of but one poison. If this be not the correct view to take of the matter, I confess myself quite unable to explain the cases of the mixed types detailed this evening; for it must have been observed, as each was given, how the symptoms of each type of fever were mixed up together. As there is not time, however, to go over each symptom in detail, I shall notice but one, on which most, if not all, who hold different views from my own, seemed to have placed the greatest weight of their argument. I mean the spots said to be characteristic of enteric fever. On this point, I think I may say with certainty that these lenticular red spots, and few in number, have not the value which has been given them; for I have seen them now in many instances, and some have been given this evening where, while they existed, there was not another symptom of the ileum being engaged—at least I could make out no evidence of such a lesion, though looking specially for it. Here, then, were cases where the particular spots existed, but not the lesion of which they are said to be diagnostic. But, further still, I have given cases to-night where, with the enteric spots, there was also a typhus rash. As bearing on this particular point, I would just recall the case of the man Develin, where the enteric spots first appeared, then the typhus rash, and as this latter disappeared the enteric spots were again visible. If this be not a case in point, I know not what is; and I shall be glad to hear some explanation of this from any gentleman who differs from me. As regards the spots of typhus fever generally, I have got an impression that a good deal of misconception exists. I have heard some speak of the bright and the dark spots, as if there were a difference between them. On this point I can state with certainty that it is very common to see the two on the same individual, and at the same time. This may be seen on the body itself, but it is more common to have the dark on the body and a bright red on the arms. Again, the spots of enteric fever are described as recurring again and again, and this is quite true. But it does not seem to be so generally known that the same may be seen in typhus, for I have witnessed cases where a distinct second crop of eruption appeared; nor is the observation original, as I have read of it in one of the older authors, though I cannot at this moment give his name. So also of the statement that petechiæ are never seen on the face. This is positively incorrect, as I have noted several cases where they were quite distinct. But these points are only mentioned here as bearing indirectly on the point under discussion. Still I think they are enough to show that any positive statements about the rash in fever must be received with caution, as the variety is truly very great. I cannot, however, pursue the subject further here.

In the course of these observations it has been stated that the enteric type of fever must be due to a something else rather than a particular poison; and if asked what that is, I would state my impression that it only occurs in persons of a peculiar constitution, most probably closely

connected, if not identical, with the strumous. This idea I have stated before; but every year is increasing my conviction on the point, and if it should turn out to be correct, I need scarcely say how important it would be. I know not whether the idea has struck any one else, but it is not stated in any of the works on the subject that I have seen. My reasons for holding this view are the following:—The enteric fever is very constantly indeed met in persons of a fine skin, and I have now seen several instances where scars, evidently strumous, existed in the neck of persons who had this type of fever. Again, it is much more common under 30 years of age—that is, when the tendency to struma is known to be strongest. I am aware that this remark may be objected to, inasmuch as every type of fever is more frequent under 30; but what I would convey is this, that whilst typhus is common after 30, 40, and 50, enteric fever is exceedingly rare. I myself have not met it in any instance above 35, though it has, I know, been seen later; but, further still, every one is aware that in the course of enteric fever the lungs are very apt to become engaged. But in place of this affection passing off with the fever, as it does in typhus, it is by no means uncommon to meet cases where signs like phthisis declare themselves. The pulse keeps up, sweating occurs, and the cough is very troublesome and hard to relieve. I have said that such is common after enteric fever, and I have been forced to send several out of hospital in this state with the hope that change of air would benefit them, and in some I know that I heard of subsequently it had proved successful. That the idea I would put forward is not without some surer foundation than mere impression, I may cite the following instance:—

Case 15.—C., a girl of 16, was admitted into the Cork-street Hospital in January of the present year. She had a very fine skin, with light eyes and hair, and laboured under enteric fever in a very well-marked form. The diarrhoea proved most obstinate; but as the abdominal symptoms yielded the lungs got very much engaged from general bronchitis of the minute tubes, and for more than ten days the dyspnoea was of the most urgent character, the lips being quite livid and the distress very great. Though the urgency of this state lessened, the pulse still kept up, and the patient began to have regular sweats, and, finally, I was able to observe that the upper part of the right lung was becoming solidified. Nor did the disease stop here, for in a period of about seven weeks I was able to trace weekly the process of softening going on, till at last a cavity formed. In this state the patient left hospital, the physical signs in the top of the lung being those of a cavity, but the rest of the lungs being apparently quite sound, and as the patient's passage had been taken for America, it is just possible the predisposition to tubercle, which seemed so strong in this girl, may be averted, and she might yet live to old age.

Lastly, on this question of the connexion, or supposed connexion, between enteric fever and the strumous diathesis, I would just advert to the great similarity which obtains between the lesion found in the fever and that which so often exists in ordinary phthisis. For my own part, I must say I have seen many specimens where I could not distinguish them, and I shall be glad to hear any gentleman express his opinion on the point.\*

The general question brought before the Association

\* It is well worth noting, in relation with the supposed connexion between the strumous constitution and typhoid fever, that the affection of Peyer's patches is not confined to the fever itself. It has been found in cases of scarlatina and small-pox, and in the *Lancet* for June 9, 1866, two cases are given, in one of which measles and the affection of the glands coexisted, and in the other Bright's disease. Facts like these seem certainly to lead to the conclusion that typhoid fever is not a specific disease, but is more likely due to some peculiarity of constitution. Whether ulceration of Peyer's patches is an essential part of this affection appears not yet absolutely settled. As bearing on this point the chapter in Louis' work, entitled "Simulated Cases of Typhoid," is well deserving of perusal.

this evening is not, as some think, one of mere curiosity. It is of every importance that it should be settled. The diagnosis, prognosis, and treatment of the disease all hinge upon it. For if typhus be the specific fever which some think it, it is obvious that the treatment will differ from what it would be were the enteric lesion present at the same time, and the danger of allowing such a lesion to pursue its course unchecked would indeed be very great. On the other hand, those who hold with myself that the two types of fever may arise from the one poison and coexist, will always be on the look-out for such a complication, and will act accordingly. For myself, I believe I have often had to deal with such cases, and to alter or modify the treatment as the case required, and that this is not a mere belief I have reserved for this part of my remarks the details of the following cases, which have, however, been on a former occasion detailed:—

Case 16.—A girl of 20 years of age was attacked with fever of a severe kind. Raving occurred and petechiæ very early, and these latter spread over the entire body. With these symptoms there was also severe diarrhoea and tympanitis. Matters went from bad to worse, and the patient died about the fourteenth day of the fever. On *post-mortem* examination the lower portion of the ileum was found extensively ulcerated, Peyer's patches being the parts engaged.

Case 17.—A boy of 14, who had already learned to drink, was attacked with fever. He had much stupor and moaning, both night and day, and he presented a copious petechial rash over the body. With this state he had also tympany and diarrhoea, and, finally, involuntary stools and death. On examination extensive ulceration in patches was found in the lower portion of the ileum. The brain presented the usual appearances found in cases of fever, but in a lesser degree than is common. I should say at the time this case occurred I was much surprised at the result of the *post-mortem*, for I then believed the enteric lesion could not exist with regular typhus, which the boy otherwise presented.

Case 18.—Hill, a girl of 18, fine skin, was admitted into hospital after being nine days' ill of fever, which presented all the signs of the enteric type, including the spots, which appeared the day after admission. These did not, however, go through the usual course of such spots. They gradually increased in numbers, spreading to the chest, arms, and, finally, the face, and in this state many of them could not be distinguished from regular petechiæ, being large, dark, and ill-defined. My colleague, as he was then, Dr. Aquilla Smith, saw the patient at this period. By the fourteenth day of the fever all the signs of enteric fever seemed to have subsided, but there was no corresponding change in the state of the patient. Her nights became restless, she shortly lay on her back, sordes formed on the nostrils, lips, and tongue, and she got great tremor of the upper extremities—in fact, she presented all the signs of well-marked typhus, and died on the twenty-first day of her illness. Except in the lower portion of the ileum nothing abnormal was found, and here the signs of disease were slight, but well marked. Peyer's patches were much plainer than natural, and this became more apparent as the valve was approached, for here one of an inch in length and a third in breadth was prominent and brought out in strong relief, but it had not ulcerated. The impression given by the inspection was, that irritation had recently been going on in the part, but had somewhat subsided. The specimen was exhibited before the Pathological Society.

Case 18.—Bellew, a servant, aged 45, of tall stature and thin, admitted in May, 1862, with all the signs of fever in a very severe form. He had to be supported into the hospital, and though only one week ill was already densely spotted; his tongue dry and brown; eyes very much injected and expression heavy. There was also severe diarrhoea, which seemed to cease suddenly within forty-eight hours—that is, about the eighth day of the fever. From this out the attack was as genuine typhus as it is possible to describe. The spots became of the darkest,

the mind very confused, with constant rambling and passing under him. There was difficulty in putting out the tongue, and, late in the illness, hiccup. By the eighteenth day the symptoms had materially improved. The spots were gone, the tongue had expanded, and was put out better, and he took support well. It was evident, however, the fever had not resolved itself. The pulse had not fallen in proportion, nor the tongue cleaned, and he still remained heavy and at times would ramble. In this state he went on till the twenty-fifth day, when he died. There was no effort at crisis at any time nor any tympany. I was only able to examine the abdomen. The ileum had no ulceration in it, but it was very red in patches, and the more so the nearer we got to the cæcum. In this last organ the chief lesion was found, for it was ulcerated in patches, one as large as a shilling. The ascending colon had a number of small and distinct ulcers in it. The glands of the mesentery were not enlarged. It is scarcely necessary to observe that Louis' observations prove that the colon is often engaged in enteric fever, similar to what has been just described.

It appears to me these cases afford as strong a proof as the nature of the subject admits that the enteric lesion may coexist with a petechial rash, or, in other words, with typhus fever. On my own mind there now exists not a shadow of doubt of the fact, and if this be not the proper view to take of the matter, I must ask those who differ from me to explain it otherwise. What has been advanced are facts, put what interpretation on them we may. Nor would the slightest difficulty exist in giving other cases, and some striking ones have occurred within the last month; but I prefer now to glance at what others have seen, for if no one else had met similar cases to my own there would indeed be strong grounds for questioning my powers of observation, and necessarily the correctness of what I have stated. I refer, then, my hearers to the lectures of the late Dr. Todd, in which they will find some cases exactly like those given this evening—that is, the enteric type of fever attended by a copious measles rash. Some of these, too, died, and the specific lesion of the intestine was found. Again, in Chambers' "Clinical Lectures" may be found cases of exactly the same kind, and also examples of the two types of fever coming from the same room. Here, then, are two London physicians who fully bear out what has been advanced this evening, and I quote them the more readily, as they have managed to see a class of cases, which, by some strange fatality, never seem to have come under the notice of Dr. Jenner and those who agree with him; but, further, I observe that Dr. Lyons when in the Crimea met the two types of fever in the combined form, and states, specially in his work, that whilst the rash was genuine typhus the lesion often found was ulceration of Peyer's patches. In a paper, too, which has just appeared by Dr. Law on "Fever," one of the cases given is described as a typhoid case, as I believe it was, and yet the rash was a copious measles one. Lastly, the Drs. Martin, from Berlin, whose names I have already mentioned, told me the two types of fever were commonly looked on as the same disease, and that the enteric type was there called abdominal typhus. I have not the least doubt that had more time been given I could have got further evidence in the same direction;\* but

\* My friend Dr. Grimshaw has directed my attention to lectures by Drs. Peacock, Barlow, and Gull. These all reside in London, and have detailed cases precisely similar to some of those given this evening—that is, the symptoms of typhus supervening on those of typhoid and petechiæ appearing whilst lenticular spots were still out. The explanation of all these, Gentlemen, is the same—that the patients caught the typhus poison at the time its symptoms made their appearance. This may be the true interpretation; but to myself it seems most difficult of acceptance, and it does not contravene the fact that the two types existed in the same patient at the same moment. Dr. Murchison has, I find, recorded similar cases, and such will also be found, and in greater numbers, if my memory serve me right, in the works of Drs. Flint and Bartlett of America.

enough, it appears to me, has been advanced for my present purpose. I do not, for a moment, assert that the question is settled on my side; but I do maintain that enough has been stated this evening to show gentlemen who differ from me the need of a cautious reserve on this question, and in not allowing themselves to come to a decided conclusion till all the facts of the case are clearly before them.

Before concluding these remarks, I would advert for a moment to one other symptom which some have thought was characteristic of the enteric type of fever—I mean hæmorrhage, whether from the nose or the bowels. The London physicians especially look on them in this light, but it certainly is not correct as regards Dublin. With us typhus often exhibits epistaxis, both in its earlier and more advanced stages. In the summer it is very common, particularly when the temperature ranges high; but it is much more frequent in some years than others. And, again, as regards bleeding from the intestines, I myself have put on record some thirty cases—most of them regular typhus—in which bleedings, more or less severe, occurred, and in some that proved fatal and were examined not a trace of ulceration was found. So that bleedings cannot in any way be considered as specially diagnostic of enteric fever, and I do believe the same may be said of any other symptom that might be chosen. I would repeat, however, that it is quite another matter distinguishing between the several types of fever. This can very usually be done, and ought, of course, always be attempted; but that the types of fever will often be found united I cannot doubt, and I think the time will come when the natural history of fevers—for this is really the question at issue—will be looked on in a very different light from what it at present is.

On the treatment of fever I have here little to say. As a single remedy, and in the ordinary typhus, I find barm still the best. It seems to me to act as an antiseptic, and to fulfil the indications required better than any other agent with which I am acquainted. I consider, too, that, to a certain extent, it supplies the place of wine; and this is no little matter to be able to say of it. Under its use the mortality, in spotted cases, has, I believe, been reduced to the lowest on record. But having spoken of these several points on a former occasion, as likewise the dose and mode of using it, and the precautions to be adopted, I shall not enter upon them further now.

Of the treatment of the enteric type of fever, I have only to repeat that, when seen early, it appears to me the most amenable of the several forms of the disease. I mention this because elsewhere, particularly in London, it seems to be a very fatal disease. Like typhus, it appears as if it were a more severe disease there than with us in Dublin.\* Though not easily accounted for, this may be so. Still my conviction is, that treatment has a more decided effect on it than any other type of fever. For myself, I use astringents, and from an early stage of the attack, and it is the dilute sulphuric acid on which I chiefly rely. This is the medicine recommended by Huss, and in the proportion of one, two, or three drachms to an eight-ounce mixture I have found it most useful. Two or three drops of kudanum are added to each ounce of the mixture, which is repeated according to the urgency of the case. It is, however, to be observed that the diarrhoea is only to be moderated, not directly checked; and this rule is the more important the earlier the disease is seen. If the diarrhoea be stopped too soon or too suddenly mischief elsewhere than in the intestines will arise. It may be in the chest, or the brain may be the organ that suffers. Several such cases have come under my notice; but though some of these were severe, none proved fatal. One, however, was so remarkable that I must give it here; for the checking the diarrhoea had, or seemed to have, the effect of altering the type of fever under my very eye.

Case 19.—Kelly, a man of 19, having a fine skin, was

\* In Dr. Murchison's very able work I find the mortality of enteric fever is put down at from 15 to 17 per cent. In my own experience, this has never been even approached.

admitted into hospital, labouring under the enteric type of fever in a well-marked form. He presented the characteristic diarrhoea, and also the spots, and had been nine days ill. After three doses of the acid mixture the diarrhoea suddenly ceased, and was at once succeeded by symptoms referred to the head. His eyes, which before had been quite clear, became deeply injected; he complained of headache, his face flushed, he began to rave, and in the course of two days he presented the countenance of a well-marked typhus case, his tongue and lips being then covered with sordes. In this state, and when now about twelve days ill, his nose began to bleed, and this was repeated daily three times, so that he bled in all on four occasions. The first of these the bleeding was much the most, and they were all so obviously beneficial that they were not interfered with. The patient made a good though very slow recovery. There was no recurrence of symptoms referable to the intestines. I have seen several instances like the one just given, but none so striking, and none which proved fatal. When, however, any similar instance occurs, it may be assumed that the case is quite within our control.

To enter any farther here into the treatment would be quite foreign to the object of this paper.

### RICHARDSON'S ETHER SPRAY PRODUCER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The adjoined memoranda which I extract from my case-book furnish, in my opinion, unquestionable proof of the value of Richardson's Ether Spray Producer as a local anæsthetic agent,—I am, Sir, your obedient servant,

F. J. DAVYS, A.B., M.D.

Swords, June 6th, 1866.

*Case 1.*—M. C., a stout and healthy young woman, applied to me at my dispensary in Swords on the 18th ultimo, expressing a desire to have a tumour removed from her arm. I recognized the patient at once, as having had two tumours of the fibro-cystic character removed at different periods within a few years from the same arm. Both tumours I had the honour of laying before the Surgical Society—the one in March, 1865, and the other in March, 1866; and the tumour which I removed within the past month formed near the cicatrices of the others, and had reached the size of a walnut, which was of the same character as the former tumours, the full description of which appears in your valuable journal in the report of the proceedings of the Surgical Society of the above dates. I was enabled to try, for the first time, the effects of the spray producer, and the patient being very desirous of having me to remove the tumour, I at once had a continuous stream of the spray directed towards it, and had the patient's head, by aid of an assistant, directed one side. As soon as the parts surrounding the tumour became blanched, I made one long free incision, extending to an inch above and below it, and I removed it without any trouble. I then allowed the patient to look at her arm. She expressed herself as marvellously surprised to know that she had been freed of the tumour so quickly and painlessly. She assured me she felt not the slightest pain during the operation, but in course of a few minutes afterwards she complained of pain when the circulation was returning to the parts. She described the pain to be such as she would feel if she put her hands when cold in frosty weather near a fire.

*Case 2.*—Mrs. W., the wife of a respectable farmer, a delicate, and elderly woman, and of a nervous temperament, was suffering for several days from paronychia on thumb of her right hand. She would rather allow her hand to slough off before she would consent to have the thumb lanced. She was becoming daily more exhausted, when it occurred to me to try the "spray producer," and having applied for some minutes the stream on the parts affected, till the thumb was perfectly blanched, and, as she then remarked, "It is now so dead with cold, I would

scarcely feel anything that would touch it." At that moment I freely opened it without causing her scarcely any pain.

*Case 3* was that of an anthrax which formed on back of the neck of a nervous, irritable young man. I applied the ether spray. The first incision he felt not in the slightest, the second (to form the crucial incision) he felt, but it was not, he said, very painful.

I may observe that each of those patients quickly recovered from their respective ailments.

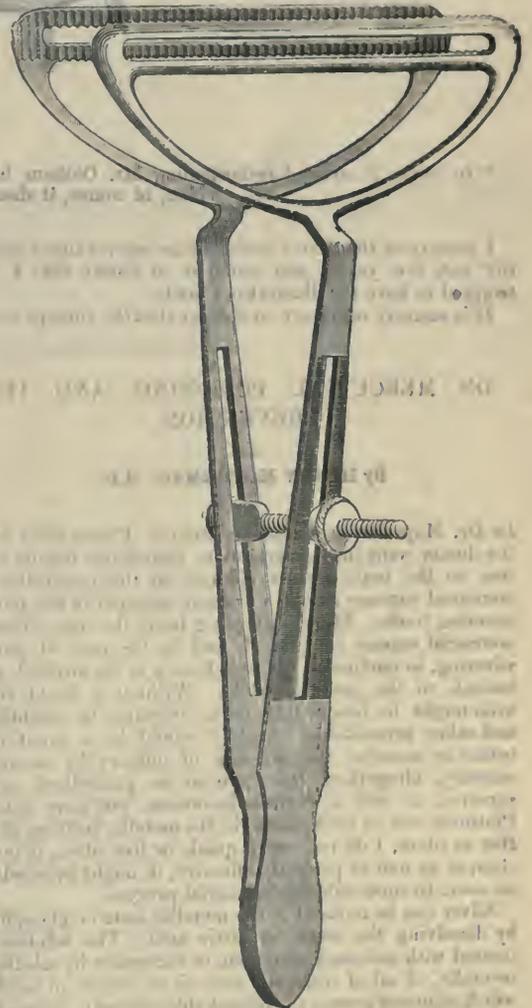

### MODIFICATION OF M. RICORD'S FORCEPS FOR THE OPERATION OF CIRCUMCISION.

By B. WILLS RICHARDSON, F.R.C.S.I.,  
SURGEON TO THE ADELAIDE HOSPITAL, DUBLIN.

HAVING found M. Ricord's forceps a somewhat unhandy instrument in the operation of circumcision, for which it was invented, I suggested to Mr. Thompson of Henry-street, some modification in its construction that appeared to me would render it more useful, and thereby, the surgeon more independent of assistants.

Fig. 1 represents the real size of the modified forceps,

FIG. 1.

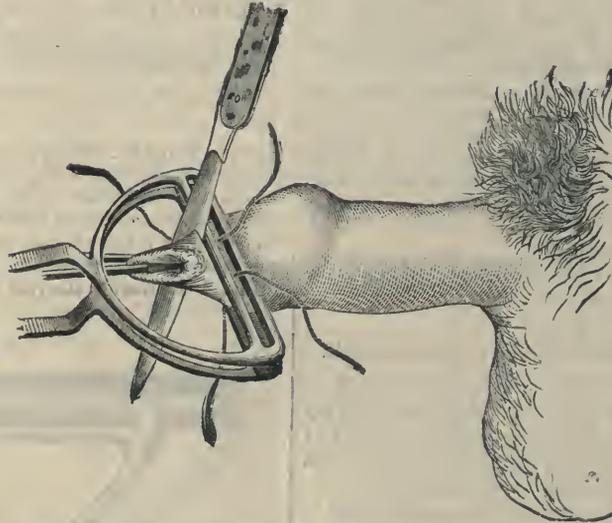

and Fig. 2 is a reduced illustration of the grasping part of the instrument *in situ*, the ligatures having been introduced and the superfluous prepuce in process of removal.

With this forceps the operation can be performed rapidly and easily, and at the same time the necessity of having an assistant is dispensed with, which, indeed, under some circumstances, the surgeon might not be able to procure.

Thus, when the forceps is fixed on the prepuce by mean

of the sliding screw and nut, the operator is relieved of the awkwardness of having by pressure of one hand to keep the jaws of the ordinary forceps closed tightly, while with the other, he is passing the needles and ligatures and removing the superfluous foreskin—a part of the operation, in which with Ricord's forceps an assistant is of much use.

FIG. 2.\*

\* In order to avoid foreshortening, Mr. Oldham has represented the forceps somewhat oblique on the prepuce, which, of course, it should not be during the operation.

I have tried the above modification several times within the last few years, and found it so handy that I was tempted to have the illustrations made.

It is scarcely necessary to observe that the forceps is also

suitable for ordinary circumcision, which some surgeons prefer to the procedure for which Ricord's instrument was designed.

Dublin, June 16, 1866.

## ON MERCURIAL POISONING AND ITS PREVENTION.

By HENRY MacCORMAC, M.D.

IN Dr. Mapother's interesting lecture, PRESS 23rd May, the doctor went into several most instructive details relative to the toxic results induced by the respiration of mercurial vapours among workmen engaged in the mirror silvering trade. The evils flowing from the respiration of mercurial vapour, in general, and in the case of mirror silvering, in particular, are well-known to the medical, and, indeed, to the general public. Without a doubt, these evils might be lessened by strict attention to cleanliness and other precautions. Still, it would be a great deal better to abandon the silvering of mirrors by means of mercury, altogether, the more so as procedures much superior, as well as entirely in-nocent, are now extant. Platinum can be precipitated in the metallic form on glass. But as silver, I do not mean quick or live silver, is much cheaper as well as perfectly effective, it ought everywhere be made to supersede the mercurial process.

Silver can be reduced to the metallic state on glass, first, by dissolving the metal in nitric acid. The solution is treated with ammonia and, then, in succession by solutions, severally, of oil of cinnamon and oil of cloves in alcohol, which solutions possess the remarkable property, in common with grape sugar, of reducing the oxide of silver to the metallic state. Petitjean's process, however, is, I believe, the one actually in vogue in France for silvering glass mirrors. I do wish and entreat that Dr. Mapother would introduce Petitjean's procedure among the mirror silvering artisans of Dublin, and so spare the poor fellows many a qualm

and care. And, with this object in view, I shall, with your kind permission, describe it briefly.

Petitjean's procedure for silvering glass. Fifteen hundred and forty grains (1540) of the nitrate of silver are treated with 955 grains of the strong solution of ammonia, our *aqua ammonia fortissima*, then 7700 grains of distilled water. To this solution, when clear, add 170 grains of the tartrate of antimony dissolved in 680 grains of water, then 152 cubic inches of distilled water are to be added with agitation. When settled, the clear liquor is to be poured off. Then, to the solid residuum add other 152 cubic inches of distilled water. The clear liquors are, now, to be put together, and add 61 inches cube of distilled water. This is silvering solution No. I. Silvering solution No. II. is to be prepared, as before, only with twice the amount of tartaric acid. A planed cast iron table, levelled with a level, and containing water at a temperature of 140° F. gas heated, is the apparatus. The glass to be silvered is well cleaned with a soft cloth, then, with a plug of cotton dipped in the silvering fluid to which a little polishing powder is added, lastly, with a second plug of dry cotton. The glass laid flat on the table, is carefully covered with silver solution No. I. spread with a cylinder of india-rubber stretched on wood and cleaned with the solution. In from ten to twenty minutes the silver begins to be deposited. After a certain time, push the glass to the table edge, tilt so as to let the fluid run off, wash and examine. The next thing to do is to pour on silvering solution No. II., after which wait, tilt, wash, and dry. Finally, cover the work with red or black varnish. These mirrors are said to cost but 1s. 8d. per square yard for silvering. They do not spot, and are otherwise very beautiful and durable.

It is our bounden duty, I conceive, not merely to remove, but to prevent disease. Workmen are to be con-

strained, if needful, in respect of the observance of proper precautions. Ignorant masters are to be instructed, while the law should step in aid of science and humanity. The simple employment of head pieces, with glass mask and a double current of air passed through tubes, a very gentle application of steam power would suffice, together with washing the hands before meals, would render the most unhealthy callings, such as dry grinding and phosphorus match making, quite exempt from risk.

## Hospital Reports.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

### THERAPEUTIC NOTES.

*Capsicum in Delirium Tremens.*—Since our last notice of the employment of this simple and efficacious plan of treatment, some well-marked cases have occurred in Dr. Lyons's practice. In one instance the patient, a tavern-waiter, of chronically intemperate habits, was admitted to the Whitworth Hospital in the first stage of this morbid condition. The patient exhibited tremor in almost all the muscles of the body, chilliness, debility, sleeplessness, foul tongue, severe and general uneasiness, but there was a total absence of illusions, horrors, or delirium to any degree. He got a single dose of capsicum, twenty grains in a bolus, after which he slept and fully convalesced, the disease having been thus peremptorily cut short. Dr. Lyons remarks on the great importance of this early phase of the disease being recognized and promptly treated. The patient is in that condition in which he may be by but slight further indiscretion plunged suddenly into all the horrors and moral degradation of the state of fully developed delirium tremens, with all its consequent loss of character with others, and loss to the patient himself of that last barrier against utter abandonment, the sense of shame and remorse. For not alone does the first occurrence of delirium tremens brand the sufferer with the character of an all but irretrievable dipsomaniac, but the fact that he has passed this moral rubicon, in the vast majority of cases deprives the patient of all stimulus to self-control, and under the demoralizing feeling that there is nothing further to be risked, his steps henceforward ever tend downwards and from bad lead on to worse.

As Dr. Lyons observes, a brief but variable period often precedes the fully developed attack of delirium tremens, especially in first cases, in which the patient presents anomalous symptoms unintelligible to himself, and not always read aright by his attendant. This stage is in some patients marked by the occurrence of tremor, sleeplessness, and general distress and anxiety, without a trace of delirium. In other instances slight illusions prevail without tremor, from which the patient can by an effort arouse himself, and under strong self-directed exertion of the will even command his faculties for a time, and pursue avocations of business, to break down, it may be, hopelessly, a few hours subsequently, if his condition is neglected, misunderstood, or mistreated. Under these circumstances the treatment by capsicum comes in very opportunely, and by its employment we may, as in the case just cited, cut short the disease, and so save the patient from the consequences of his imprudence, and possibly restore him to a reformed life. Another case well illustrates the success of this drug when opium had completely failed to alleviate the symptoms, and seemed on the contrary in many respects to aggravate the patient's condition. The case was that of an individual who had taken six grains of opium within a period of two or three days without sleep being procured, or any relief to the illusions, tremor, and distress under which the patient laboured. After a twenty-grain dose of capsicum in

bolus, profound and refreshing sleep for twelve hours was induced, and the patient awoke conscious and restored. In an almost precisely similar instance occurring about the same period a thirty-grain dose of the drug had to be given a second time before full relief was procured. In one or two instances of individuals of confirmed and extremely intemperate habits it was found necessary to repeat the dose some three or four times.

As to the physiological action of the remedy, Dr. Lyons's explanation is that already given in a former communication—namely, that it produces a powerful stimulant and sedative influence by its direct action on the gastric filaments of the vagi. Slight uneasiness in the stomach has been complained of in one instance only after its use, and in two instances somewhat smart purgation was noticed, but without any evidence of intestinal or other irritation.

As at present employed, the drug is administered in bolus made up with honey of roses; but Dr. Lyons suggests the feasibility of its being conveyed to the stomach in the more agreeable form of a capsule.

As capsicum belongs to the great order of the Solanaceæ, Dr. Lyons suggests the possibility of its containing a narcotic principle hitherto undiscovered. He has referred this question for further elucidation to his distinguished friend, Mons. Gages, curator of the Museum of Irish Industry, a chemist of great eminence.

Christison observes, "Capsicum and cayenne pepper belong to the class of irritant poisons; and the latter preparation has been known to cause death. It is entirely destitute of narcotic properties, so far as is known at present. In both respects it constitutes a singular anomaly in the natural order Solanaceæ, which are generally powerful narcotics, but feebly or not at all acrid."

Pepper (*Piperaceæ*) probably black pepper, was not unknown to the ancients medicinally. Celsus, it may be mentioned, has a chapter headed: "Curatio horroris in febribus Si nec balneum quidem profecit, ante accessiorem allium edat aut bibat calidam aquam cum pipere, siquidem ea quoque assumpta calorem movent qui horrorem non admittunt." Dioscorides also alludes distinctly to the use of pepper in curing the shiver of fever, and in later times Van Swieten and Louis Frank have employed it for a like purpose. Under the form of piperin the active principle of black pepper has been by many practitioners in the present century prescribed in the treatment of fevers, some vaunting its efficacy as not second to that of quinine.

*Chlorate of Quinia.*—This newly-discovered salt, which the profession owes to Dr. Lyons, continues to be employed in his Clinique and in his private practice, we are informed, with most satisfactory results. In cases of scarlatina, typhus, all low pyrexial states, local inflammations, &c., the use of this drug is indicated, and so far as opportunities have yet been afforded for testing its efficacy, the results are reported to be highly favourable. From its chemical constitution and the large amount of available oxygen which is thrown into the system when this medicine is ordered, according to the formula recently furnished\*, in solution with perchloric acid, valuable therapeutic effects may be anticipated *a priori*. The tonic alkaloid conveyed into the economy at the same time is a very important substitute for the potash in the ordinary salt hitherto employed (chlorate of potash). Dr. Lyons awaits an opportunity of testing the value of the chlorate of quinia in that malady in which, above all others, chlorate of potash has attained, according to Trouseau and Pidoux, its most important and indisputable triumph—namely, gangrenous stomatitis. Meanwhile he invites the co-operation of his professional brethren in testing the value of this hitherto unused salt.

*Syrup of the Phosphates of Iron, Quinine, and Strychnia.*—Dr. Lyons has for some time past employed with, he conceives, very important therapeutic results, this powerful tonic combination, for which the profession is mainly indebted to the late Dr. Eaton of Glasgow, and Professor Aitken of the Royal Victoria Hospital, Netley.

\* See *Medical Press and Circular*, May 30, 1866.

The concentrated syrup of the phosphates, when made by double decomposition, according to Professor Aitken's formula, contains per drachm two grains of the phosphate of iron, one grain of the phosphate of quinine, and one thirty-second of a grain of the phosphate of strychnia. It is a perfectly clear and limpid fluid, slightly refracting light with the peculiar tint of the quinine solutions, and, viewed in mass, obliquely showing the bluish tint of the phosphate of iron held in solution. It is perfectly miscible with distilled water, has a strong styptic and distinctly chalybeate taste, and an aftertaste of quinine. It may be exhibited in doses of twenty to forty, and even sixty, minims, diluted with water, according to age and the circumstances of the case. It is well borne in the majority of cases; it acts as an invigorating stomachic and sensibly improves appetite; it is an admirable general tonic; it appears to be a readily assimilable chalybeate, and is thus well adapted for certain chlorotic and anæmic states. In the morbid states of the nervous system which precede and accompany the development of the strumous diathesis, the influence of the strychnine salt appears to be exercised with great potency as a nervine tonic and stimulant, and it would seem to be an important agent in altering the morbid state of the nervous apparatus which presides over the function of nutrient assimilation. Physiologically, this influence may be supposed to be attributable to the well-known action of the strychnine salts on the spinal cord, as well as by direct stimulus to the filaments of the great sympathetic plexuses distributed to the stomach and intestines. From the general tonic and invigorating effect of this drug, its influence on the stomach and the promotion of appetite, as well as by the improved assimilation of food which it induces, it is a very valuable medicine in cases of strumous children threatened with scrofulous degeneration and ultimately with localized tubercular development. As a preparative to the use of cod-liver oil, and in certain cases as a concomitant to this food-substitute, the syrup of the three phosphates will be found a very important adjunct in the treatment of numerous forms of strumous disease.

But the employment of this admirable combination is not limited to the cases just mentioned. In depressed state of the system in the adult and aged, in several of the conditions tending to adipose degeneration of important organs, such as the heart and kidneys, the syrup of the phosphates will be found a serviceable and reliable remedy. Where it is desired to combine a tonic and styptic to aid in checking the drain of albumen from the system in chronic disease of the kidneys, this combination will be found of great use.

In many forms of cutaneous diseases where a tonic effect is desired, this combination will be employed with benefit.

For the use of strychnia in chorea and certain other of the maladies of children, the high authority of Trousseau and Pidoux may be cited. These distinguished authors give the following formula for the preparation of a syrup of strychnia. Five centigrammes of the sulphate of strychnia are dissolved in one hundred grammes of simple syrup. One hundred grammes contain about twenty-five *cuillerées a café* or teaspoonful; each teaspoonful or drachm contains two milligrammes or one twenty-fifth of a grain of the sulphate of strychnia. Dr. Lyons is of opinion that a superior efficacy will be found to attach to the triple combination above described. His best thanks are tendered to the Army Medical authorities in this city, by whose kindness Serjeant Moss of the Army Medical Stores, himself an experienced practical chemist, and who had learned the process under Dr. Aitken's supervision, has been allowed to prepare for him a specimen of the syrup of the phosphates of iron, quinine, and strychnia in exact accordance with Professor Aitken's directions.

## MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

### CASES UNDER THE CARE OF MR. PORTER,

SENIOR SURGEON TO THE HOSPITAL.

[Reported by ARTHUR WYNNE FOOT, M.D.]

(Continued from page 506.)

#### CHRONIC HYDROTHORAX—PARACENTESIS THORACIS—DRAINAGE TUBE EMPLOYED.

*Case 16.*—John Grainger, 24 years of age, a patient in the medical wards, required relief from a large amount of liquid effused into the left side of the chest. The heart was displaced, its apex pulsated to the right of the right nipple; the left side of the chest was inelastic, dull on percussion, and almost motionless, measuring twenty inches and a half, the right measuring nineteen inches. Dyspnoea, loss of sleep, and hectic fever made an operation for the evacuation of the fluid necessary. Mr. Porter punctured the left side of the chest on the 4th of May by passing a narrow-bladed scalpel directly into the cavity of the pleura between the fifth and sixth ribs.

A piece of perforated india-rubber piping was then introduced, one end of it being allowed to hang out of the wound, 304 fluid ounces of sero-purulent matter, having a specific gravity of 1022, came away, 172 ounces within one hour after the operation, and 132 ounces between eleven a.m. and three p.m. The patient's condition became at once materially improved; the heart returned towards its normal condition rather slowly, inasmuch as the effusion had existed for a considerable time. He was so much restored in appearance that his father removed him from hospital before he was quite convalescent.

#### INDOLENT AND PAINFUL ULCER OF THE LEG, TREATED WITH OPIUM.

*Case 17.*—A woman between 50 and 60 years of age, was admitted under Mr. Porter's care, with an ulcer on the lower part of the leg which had existed more or less for eleven years. It had at times partially healed up, but never completely, and upon admission measured three inches in one direction by two in another; an indurated "well" formed its margin, the depressed floor was pale, covered with a pinkish grey mass of feeble granulations, discharging but little, and that a thin purulent matter of great factor. Her chief complaint was of excessive local pain, depriving her almost totally of sleep at night. This symptom was one comparatively recent, and made her most anxious for relief; as to the healing of the ulcer itself she was not much concerned about that, as she had become quite accustomed to it, and had long given up hopes of having it cured. The especial nocturnal severity of the pain, its recent occurrence, and the evident proximity of the floor of the ulcer to the bones of the leg made it very probable that the acute pain was connected with periosteal inflammation. She was kept in bed, lotion of chloride of lime applied to the ulcer, and half a grain of the watery extract of opium given night and morning. This dose very much subdued the pain and was further increased to a full grain twice a day. She obtained her natural sleep at night without suffering from constipation or exhibiting any symptoms of narcotism. Mr. Porter frequently remarked, during the progress of the case, upon the benefit derived from the use of the preparations of opium in such ulcers—a remedy brought under the notice of the profession in 1837 by Mr. Skey as capable of exerting an almost specific power in healing the "chronic or callous ulcer affecting the legs of old persons." Mr. Skey, in his treatise "On a New Mode of Treating Ulcers and Granulating Wounds," says that in many cases a very palpable effect is produced by eight drops of the tincture of opium twice a day; but that he rarely commenced with a less dose than half a grain of the extract night and morning, increasing it when necessary up to two grains twice a day.

A PREPARATION of paraffin devoid of smell or taste has been made, which, it is said, will preserve meat for an infinite time.

## FATTY TUMOUR ON THE BACK—EXCISION.

Case 18.—Christopher McKenna, 45 years of age, was admitted with a fatty tumour the size of a large cocoa nut, situated between the base of the left scapula and the vertebral column, superficial to the rhomboid muscles. It was first noticed nine years ago, at which time it was the size of a bean. It was movable, painless, elastic without fluctuation, and its lobulated shape could be recognized when the skin over it was made tense by compressing its base and borders. There was no account of any injury having been received in its neighbourhood, except a dislocation of the left shoulder in early youth. A single median incision was made over the tumour, which, along with its tough investing capsule, was pulled and scooped out of its bed; two vessels required ligature, the edges of the wound were brought together by three points of iron-wire suture, and a thick pad of lint and bandage applied.

## VENOUS ERECTILE TUMOUR ON THE FACE—TREATMENT BY FREQUENT PUNCTURE WITH RED-HOT NEEDLES.

Case 19.—The subject of this case, a little girl under twelve months of age, was born with a very small nævus on the left cheek, over the malar prominence. After birth rapid enlargement of the "mark" caused the mother of the child to apply for advice about it, when the child was six months old. A venous erectile tumour occupied then the greater part of the left cheek, encroaching upon the lower eyelid and side of the nose, swelling and getting deep purple in colour when the child cried. A glover's triangular needle, fixed in a wooden handle, was heated to redness in the flame of a spirit lamp, and plunged three times into the tumour in different directions; a pad of lint was then tightly secured over the part. This plan of treatment has been followed for some months at intervals of a week between each operation, with the result of very much diminishing the size and the vascularity of the tumour, which is also becoming consolidated. No marks remain on the skin from the punctures; occasionally a drop of blood followed the withdrawal of the needle.

Case 20.—Christopher T., aged 11 years, fell from the step of an outside car on the 23rd May, 1866. Received Colles' fracture of the left radius. Deformity most marked at once. He suffered great pain all that night, and was brought to the Meath Hospital on May 24. Mr. Porter applied Gordon's splint. Much relief afforded by this position. June 15th, the forearm perfectly straight, and the fracture firmly united. This case exemplifies, in a remarkable manner, the advantages of this mode of treating this particular fracture—the freedom from pain in the prone position, the ease from allowing the fingers a certain amount of motion, and the straight recovery, from the wooden pad of the splint filling up the natural cavity of the bone.

[NOTE.—We have on hand some important cases of Aphasia with Hemiplegia, which occurred under the care of Dr. Moore at Mercer's Hospital, and we hope to publish them in our next.—ED.]

THE Commons Committee has reported with regard to the City Corporation Gas Bill that its preamble is not proved. The construction of works at a distance from the denser parts of the metropolis, which was one of the most important elements of the corporation scheme will, therefore, in this instance at least, be deferred. The result seems to have taken everybody by surprise, but is not wholly to be regretted, because it will surely tend to the accumulation of forces on the subject of gas-manufacture in London, and produce some comprehensive and irresistible measure. This will, we trust, ensure the expulsion of gas-factories from this metropolis, as was done some years since in Paris with the best results. The city scheme aimed only at the construction of works at West Ham, so as to supply the city itself. West Ham, however, convenient in other respects, is not remote enough, and, whatever, it may be a few years hence, is by far too thickly peopled a district, even now, to admit gas-factories with security to health in general and safety in explosions.

## Foreign Medical Literature.

TWO CASES OF TUMOUR OF THE BRAIN,  
WITH REMARKS ON THE  
CONNEXION BETWEEN CEREBRAL TUMOURS  
AND AFFECTIONS OF THE RETINA AND OF  
THE OPTIC NERVE.

By W. KOSTER.

Translated from the *Nederlandsch Archief voor Genees- en Natuurkunde*, 1e Deel, 4e Afl. Utrrecht, 1865.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

It is only within the last few years that, with the aid of ophthalmoscopic investigation, a peculiar morbid change of the retina and of the optic disc has been assigned a place among the causes of amaurosis. It was A. von Graefe, who in 1860 first demonstrated the connexion of this change: inflammation of the papilla of the optic nerve and its surroundings, with tumours within the cranium.\*

I had by chance the opportunity of examining, within a short space of time, two cases of cerebral tumour, which had, during life, given rise to the optical changes in question. I shall relate the brief histories and the description of the post-mortem examination of these two cases, appending to each the pathological and clinical remarks suggested by them. In conclusion, I shall add a few words upon the connexion between cerebral tumours and affections of the eye.†

a. *Sarcoma fuso-cellulare and glioma cerebri. Convulsions and paresis during life. Blindness from pressure on the optic nerve.*

Cornelia de Liefde, aged 7, a native of Nieuwediep, was admitted on the 8th December, 1864, into the Netherlands Hospital for Affections of the Eye. As to her history, it was ascertained that both her parents enjoyed good health, and that her four brothers and sisters were likewise healthy. Her mother suffers from a slight degree of cyphosis, contracted in youth.

The patient herself was healthy until her fifth year; but from that period she complained of repeated attacks of headache, occasionally combined with restlessness and spasmodic movements. On one occasion she had even an attack of furious delirium, striking with her hands to the left, and with hallucinations (especially seeing animals about her).

On the 6th September, 1864, she became confined to bed with constant headaches and exhaustion. The physician who attended her, now and then applied leeches to the temples, and prescribed powders (probably calomel). At the end of four weeks she appeared to be somewhat better, but after the patient had left her bed it was remarked that her vision was gradually lessening, while a certain progressive blunting of her mental faculties was perceptible. She had not as yet, however, any decided fits.

On the 8th December she was brought to the Netherlands Hospital for Diseases of the Eye. The pupils are wide and

\* A. von Graefe, Ueber complication von Sehnerven-entzündung mit Gehirnkrankheit. [On the complication of inflammation of the optic nerve with cerebral disease.] *Archief für Ophthalmologie von Arlt, Donders und von Graefe*, 1860, Bd. V11. Abth. 2, p. 58.

† From the essay itself it will appear that I am indebted to Professor Donders and Dr. Snellen for the clinical and ophthalmological details, while the former also in great part supplied the materials for the pathologico-histological description of the eyes.

little movable; there is no indication whatever of the perception of light. With the ophthalmoscope no abnormality is discovered except whiteness of the papillæ, with somewhat constricted vessels. The eyes have a normal degree of tension, perhaps somewhat inclining to too great firmness. The diagnosis is: *amaurosis e causa cerebri*; *prognosis infauitissima*. At the solicitation of the father and especially at the request of the child herself, who had at home probably very insufficient care, she was taken in for observation. All the other organs are normal, the bowels, at first confined, have become quite regular under the use of some syrup of senna. The appetite is irregular, sometimes she feels excessive hunger, so that immediately after a good dinner she will devour a large piece of bread with unnatural eagerness; slight convulsive movements, especially of the arms, still continue.

The poor patient has frequent attacks of violent headache and then especially exhibits abnormal movements of the arms and legs resembling chorea, which are seldom entirely absent. The nights are almost always sleepless, and are spent in constant gentle moaning. By day she is quiet and contented, but she has, although she is quite conscious and perfectly understands all questions put to her, often great difficulty in finding the words she wants; it evidently troubles her to look for them. We have seen her spend quarter of an hour in the endeavour to utter the word "mutsje" (little cap), which she wanted for her doll, which was during the whole day constantly with her.

In the night of the 22nd December she was very restless, with attacks of oppression and anxiety. It was evident that she was annoyed by apparitions, which she endeavoured to escape from by hiding herself under the clothes, exclaiming: "I must go away," "there they come," &c. In the morning at six o'clock she became quiet; at eight she was dead, without having presented any further remarkable symptom.

On the following day I examined the body. In the thoracic and abdominal cavities no abnormality was met with, so that the contents of the cranium alone require an accurate description.

The bones of the skull were properly developed, but were thin, in the situations of the future sutures they were very firmly connected, but without the existence of synostosis. The dura mater was only loosely attached to the inner surface of the bones, its sinuses contained much fluid blood. On removing the dura mater it was seen that the brain was unusually strongly compressed. There was scarcely any appearance of convolutions and sulci, the surface being smooth and flat. Notwithstanding the vessels of the pia mater contained a large quantity of blood. The cerebral mass itself was very soft and pappy, the cortical substance was reddish, the white was very pale, exhibiting on section only a few points of blood. The left hemisphere was, moreover, much larger than the right, and had pushed the latter aside.

In the middle of the white substance of the posterior lobe of the left hemisphere was found a tumour of oval form, and about as large as a small lemon. It was loosely surrounded by the displaced white substance, was continued anteriorly into the lateral ventricle, lying against the posterior part of the thalamus of the optic nerve of the same side, still covered, however, by a layer of white substance. Posteriorly the white substance, on which the tumour bordered, was oedematous, infiltrated and softened, and on incision literally flowed from the tumour. The surface of the latter was not quite smooth, but was slightly nodulated, and was of a greyish-red colour.

On cutting into the tumour it seemed to have internally a greyer tint than on the surface, and to contain much fluid and blood, its consistence was nearly that of medullary cancer. On the outer and under side was a tolerably fresh coagulum of blood, and the tumour was infiltrated with blood.

The right lateral ventricle of the brain was distended with a great quantity of clear pale serum (about two ounces). Serum was present also in the middle and left

lateral ventricles, but in the latter there was comparatively little in consequence of the proximity of the tumour.

The parts at the base of the skull were very much compressed, especially the much flattened optic nerve, and the vessels contained but little blood. There was scarcely any subarachnoid fluid.

The eyes were taken out with the whole of the optic nerve, and were preserved for more accurate examination. It at once struck the eye that the sheath of the part of the optic nerves which lies in the socket, was swollen and as if distended with fluid.

Microscopical examination of the moist surface of the divided tumour at once exhibited a great number of elegant fusiform cells, with long processes, others being multipolar and connected by their processes with neighbouring cells. At the same time many round regular little cells with a small nucleus were seen in the field of vision; together with blood-corpuscles. The first impression, therefore, was that the tumour should be regarded as a soft cancer with many bloodvessels (*fungus hæmatodes*). Closer investigation, however, soon showed, and especially after inspection of sections both of the fresh tumour and of hardened portions, that its structure agreed not with that of cancer, but of some sarcomatous tumours.

The fusiform cells connected with one another by out-runners in a reticulated manner, did not, however, as at first appeared to be the case, form absolutely a regular stroma, but the tumour consisted in great part simply of bi- or multipolar elongated cells lying close to one another. Between them occurred spots, containing little round cells all of similar size, which cells were situated in a very fine fibrous stroma present only in small quantity.

The tumour, therefore, agreed in structure chiefly with the fibro-plastic tumours (the fusiform-cell sarcoma of Virchow)\*. The spots with finely fibrous stroma and round cells bore a close resemblance to the so-called gliosarcomata.† The hæmorrhage in the tumour was evidently of fresh origin. The extravasated blood had as yet undergone but little change.

The examination of the eyes, partly in the fresh, partly in the dried state, or hardened in H. Mueller's fluid, brought little of change to light. In the yellow spot of the fresh preparation there was no trace of change, but Donders and I obtained a view of the cone of the fovea centralis, more beautiful than is usually seen. The most important change was perceptible microscopically in the optic nerves. The outer sheath of the part lying within the globe was distended with oedematous infiltration of the connective tissue uniting it with the inner sheath. In that connective tissue we found ellipsoidal clear non-nucleated cells in the separate fasciculi, into which the connective tissue is so characteristically divided.

Sections of the optic nerve gave but little information. A somewhat atrophic condition of the nerve-bundles was, however, not to be mistaken; moreover, a slight granular change of the nervous medulla was here and there demonstrable. Especially close to the papilla had the nerve-fibres undergone a granular alteration, and free fat was observable between them. In the chronic acid preparations the axis-cylinders in the course of the optic nerves still distinctly struck the eye. The interstitial connective tissue had undergone no perceptible change.

The fibrous layer around the papilla of the optic nerve was turbid, the connective tissue, however, contained no new formations, but was dark and opaque.

The retina around the macula lutea exhibited no striking abnormalities. On the addition of a weak solution of soda no fatty deposit was visible.

It is not necessary to add much commentary upon the above case. That the neuroglia of the white substance of the left hemisphere of the brain was in this instance the starting point of a process of new formation, that this

\* *Die Krankhafte Geschwulste*, Bd. ii., 1te Hafte, p. 195.

† Virchow, l.c., p. 202.

new formation began about two years before the death of the patient, proceeding at first slowly, latterly more rapidly, and that all the morbid phenomena, including the blindness, depended partly on the irritation, partly on the pressure, caused by the tumour formed, is evident without further proof.

It may be considered remarkable that in this instance, notwithstanding the existence of such an extensive tumour, a not inconsiderable degree of dropsy of the ventricles of the brain existed; and we can scarcely imagine how the brain, with such a degree of pressure, could still perform its functions tolerably well. It is, no doubt, most probable that the dropsical effusion did not take place until the very last days of life (perhaps in the last severe attack of oppression before death), under the influence of cerebral congestion, with which likewise the fresh effusion of blood into the tumour may be brought into connexion. Up to this time the slow increase in the size of tumour may, if not wholly explain, at least on the ground of analogy, make the comparatively slight symptoms of pressure on the brain more comprehensible. A further consideration of the seat of the tumour, and of the nature of the deviations caused by it, in connexion with the morbid symptoms, is (even if it were possible), as little part of our plan, as a detailed essay on the structure of the tumour from a pathologico-histological point of view, or in particular on the difficult theory of the sarcomata. I think I have described the nature of the tumour with sufficient accuracy, and in the third part of this paper, I shall revert to some peculiarities respecting the local influence of the same.

(To be continued.)

## ACTION OF OXYGEN ON THE BLOOD.

By M. SCHOENBEIN,

PROFESSOR OF CHEMISTRY IN THE UNIVERSITY OF BALE.

Translated by THOMAS WHITESIDE HIME.

FROM numerous experiments I am convinced that ordinary oxygen cannot produce any oxydation unless it has previously undergone an allotropic alteration. I have proved that there exists two distinct modifications of oxygen, antozone and ozone, or, as the author once called it, "Schoenbein's smell," which are produced in ordinary oxygen under favourable circumstances.

From experiment we know that ozone oxydises at a low temperature, and directly, a great number of simple and compound bodies. Antozone, on the contrary, is chemically indifferent to substances readily oxydisable—*e.g.*, phosphorus, pyrogallie acid, hæmatonalin, &c., but it combines readily with water HO to form peroxide of hydrogen HO<sub>2</sub>. Ozone does not combine with HO.

One means of decomposing neutral oxygen into antozone and ozone—that is, of chemically polarizing it—is to bring it into contact with a substance which can be readily oxydised by ozone and with water.

The slow combustion of phosphorus in moist atmospheric air, I consider a type of all slow oxydations in air. We must look for the cause of all the slow oxydations which appear to arise from the influence of oxygen in the chemical polarization of the neutral oxygen.

In all these oxydations oxygenated water HO+antozone is produced, without, however, the necessary liberation of free ozone. The formation of free ozone by the side of HO+antozone, during the slow combustion of phosphorus is due, as I have proved, to the volatility of the latter. In fact, it has been proved that no substance can give out free ozone during slow oxydation, unless it be volatile at the ordinary temperature or at that of boiling water. When at the ordinary temperature, or at a temperature slightly elevated, an amalgam of lead is agitated with oxygen and water acidulated with SO<sub>3</sub>, a large quantity of peroxide of hydrogen is immediately formed, without the least trace of free ozone being perceptible. This depends on the fact

that the ozone which is developed on the lead serves to oxydise the metal, as is shown by the formation of P<sub>2</sub>O<sub>5</sub>, SO<sub>3</sub>, which accompanies this reaction. The absence of ozone can be shown in other phenomena of oxydation when oxygenated water is produced—*e.g.*, when pyrogallie acid is treated with a solution of potash in presence of oxygen. In the solid state this acid oxydises neither in the presence of neutral oxygen nor of antozone, whether free or in combination with water. Ozone, on the contrary, and its combinations, the ozonides, seize it with avidity and convert it into brown substances termed ulmic.

Pyrogallie acid, when brought into contact with ordinary oxygen in presence of water, undergoes an analogous decomposition; it is for this reason a solution of pyrogallie acid becomes gradually brown on exposure to the air. The addition of an alkaline oxide hastens the decomposition.

I have proved that this oxydation is always accompanied by the formation of oxygenated water HO+antozone, which water exerts no oxydising action on pyrogallie acid. From whence I conclude that neutral oxygen is chemically polarized in presence of pyrogallie acid and water, similarly as in the slow oxydation of phosphorus in moist air. The ozone which is produced oxydises the pyrogallie acid, while the antozone unites with the water to form HO+antozone.

Spirits of turpentine also exhibits curious reactions. According to my observations it decomposes ordinary oxygen into antozone and ozone; the ozone converts part of the spirits of turpentine into resin, while the antozone acts on the other part, with which it forms a combination which can in turn give it up to other substances—*e.g.*, to SO<sub>3</sub>.

In a great number of oxydations there is formed neither ozone nor oxygenated water in a free state. This would seem to prove that neutral oxygen can produce direct oxydation, which would be contrary to my theory; but I proceed to show that there are accessory circumstances which prevent the formation of ozone and oxygenated water in a free state during these oxydations. The facts which I have mentioned lead to the conclusion that those oxydations which are produced in the interior of the organism, take place in a manner similar to the slow oxydations of a large number of organic and inorganic substances in moist air. Oxygen introduced into the body by respiration produces oxydations in it. I believe that these oxydations are always preceded by the chemical polarization of the neutral oxygen. Oxygenated water being produced in the oxydation of a large number of substances, and its presence being sufficient to show the chemical polarization of the oxygen, I have searched for oxygenated water and ozone in the blood of animals.

The examinations which I have made for this end have not shown me the least trace of either one or the other, in spite of the precautions I have used, and the extreme sensibility of the reagents employed.

This negative result, far from appearing to me a contradiction of my theory, leads me to suppose some accessory circumstances must impede the formation of oxygenated water, as well as ozone. I proceed to examine these circumstances more minutely.

In my previous researches on the action of ozone on organic substances, I have found that blood absorbs it very rapidly; that albumen, fibrin, and the blood-globules produce individually the same action on it. These substances under these circumstances undergo a remarkable change in their chemical composition, as my experiments and the interesting researches of MM. Hiss and Goup prove.

With regard to the action of oxygenated water on albumen in solution, I find from experiment that the two substances may remain a long time in contact at the ordinary temperature without sensibly acting on each other.

A mixture of these two substances, preserved during several months, still contained oxygenated water, and the amount of albumen remained unaltered.

Thenard discovered the curious property which the fibrine of coagulated blood possesses of decomposing  $\text{HO}_2$  into water and neutral oxygen, without itself becoming oxidized in an appreciable degree. Does the fibrine in solution in the blood possess the same power? This cannot be asserted with certainty, for no one that I know of has hitherto succeeded in obtaining fibrine in a liquid state out of the body.

I have found that fresh blood, carefully deprived of its fibrine, possesses in a very high degree the power of decomposing oxygenated water into neutral oxygen and water; the abundant disengagement of gas and the frothing produced immediately on the two liquids being mixed, renders this visible. If this gas be collected and analyzed, it will be found to possess all the properties of ordinary oxygen. Thus we see that defibrinated blood decomposes peroxide of hydrogen  $\text{HO}_2$  in the same manner as platinum—that is, into  $\text{HO}$  and oxygen. If to a certain quantity of this blood be added a relatively small quantity of oxygenated water, after some seconds no trace of it will be perceptible, and the resultant liquid possesses the quality of decomposing a fresh quantity of oxygenated water with disengagement of oxygen.

After waiting till this new quantity of oxygenated water has been decomposed, which can be readily proved by the use of *iodide of starch* and sulphate of iron, an additional quantity of oxygenated water may be added, and will be found to disappear after a little time. This cannot, however, be indefinitely continued. The blood loses by degrees its property of decomposing oxygenated water, the liquid becomes clearer and clearer, and at length becomes quite colourless, at the same time having become incapable of decomposing a fresh quantity of  $\text{HO}_2$ .

The organic substances contained in defibrinated blood are, as we know, albumen and the blood-globules. As albumen exerts no action on peroxide of hydrogen, we must conclude it is the globules which impart to defibrinated blood the decomposing properties above mentioned. What confirms this view is that the globules, when cleared as much as possible from albumen, and even dried, decompose oxygenated water, with an active disengagement of neutral oxygen.

Further, the blood-globules are being destroyed while the oxygenated water is being decomposed; and when the blood has lost the property of decomposing  $\text{HO}_2$ , it has been completely decolorised. An additional proof is that the decolorised blood no longer turns tincture of guaiacum blue in presence of peroxide of hydrogen. Blood-globules on addition of tincture of guaiacum and oxygenated water produce a blue colour, so characteristic that a very slight trace of the globules can be recognised in this manner. Water coloured with defibrinated blood, so as to be but slightly red, turns a mixture of tincture of guaiacum and oxygenated water blue, markedly and quickly. I recommend this reagent, the most delicate I am acquainted with, to the notice of physiologists and of those who interest themselves in the application of chemistry to medical jurisprudence.

The following fact will give some idea of the large quantity of oxygenated water which can be decomposed by blood-globules:—One gramme of fresh defibrinated blood will decompose, at a temperature of  $7^\circ$ , in twelve to fifteen minutes, the oxygenated water produced by five grammes of  $\text{BaO}_2$  contained in one hundred grammes of water. The resultant liquid will not have entirely lost its power of decomposing  $\text{HO}_2$ , nor will the globules contained in it be all destroyed. The colour of the liquid will still continue red, proving their presence, which can be further proved by the use of the tincture of a mixture of guaiacum and oxygenated water, which will become blue if a certain quantity of this fluid be added to it. To deprive it entirely of the power of decomposing  $\text{HO}_2$ , or turning tincture of guaiacum blue, a fresh quantity of oxygenated water, equal to what was first employed, must be added. It is almost unnecessary to add that this last supply of oxygenated water will be decomposed much more slowly than the first.

In conclusion, we find that the globules contained in one gramme of defibrinated blood will decompose two grammes of  $\text{HO}_2$ —an enormous quantity relatively to the amount of organic matter which has produced the decomposition.

The following is another very curious fact:—During the reaction of the oxygenated water on the defibrinated blood, a white flocculent substance is formed, which possesses all the properties of an albuminoid, besides that of decomposing oxygenated water, without itself undergoing any appreciable modification. This last circumstance supports the supposition that this substance is nearly allied to the coagulated fibrin of blood, if it be not identical with it, and that it arises from the blood-globules destroyed by  $\text{HO}_2$ . It devolves on physiologists to make us better acquainted with this substance. The presence of this substance gives to blood which has been completely decolorised by  $\text{HO}_2$  the property of still decomposing sensibly oxygenated water. The liquid can no longer decompose  $\text{HO}_2$  if this white matter be eliminated in filtering. If, however, the filtered liquid, although clear, be not entirely decolorised, if it have a very slight brown or yellow tinge, it will decompose a further quantity of peroxide of hydrogen, and become sensibly clouded. It must be added, however, that this substance, so analogous to fibrin, loses by degrees its property of decomposing oxygenated water, and becomes modified in such a manner as to be able to remain entire days in contact with  $\text{HO}_2$  without decomposing an appreciable amount of it. In this state it exhibits the same inactivity in presence of  $\text{HO}_2$  as the white of egg, liquid or coagulated. According to my experience, fibrin, too, loses at length its property of decomposing  $\text{HO}_2$ .

There occurs in the blood a continuous series of oxydations analogous to those which a number of organic and inorganic bodies undergo under the influence of atmospheric oxygen at the ordinary temperature, and in the presence of water. If we find in the blood neither ozone nor antozone combined with water ( $\text{HO}$ ) in appreciable quantities, we can explain their absence by the aid of the preceding facts. Albumen, fibrin, and blood-globules, placed separately in contact with ozone, unite with it with greater or less avidity. Thus we see that if neutral oxygen separates in the blood into antozone and ozone, this ozone immediately produces oxydations, and disappears according as it is formed, without its presence in the blood in a free state being demonstrable. With regard to the corresponding antozone, it is decomposed by the blood-globules at the moment it unites with water to form  $\text{HO}_2$ . If the fibrin in solution in the blood acts in presence of oxygenated water, like coagulated fibrin, it hastens the decomposition of the peroxide of hydrogen. It is then as impossible to find oxygenated water as free ozone in the blood, supposing both are continually produced by the inspiration of neutral oxygen.

The property which the blood-globules possess of decomposing peroxide of hydrogen, and thus transforming themselves into a fibrinous substance, is well deserving of the attention of physiologists, who have for a long time attributed an important action in respiration to these globules, though still not accurately determined.

If we consider, further, that of all known animal substances, the blood globules and coagulated fibrin alone possess the property of decomposing oxygenated water, like platinum, and that these two substances, with albumen, form the sum of the organic constituents of the blood, it is hard to consider this decomposing property of the globules as accidental, and without any reference to the physiological action they are destined to perform in the organism.

(To be continued.)

As the system pursued at the lunatic asylum at Yar-mouth has not been productive of satisfactory results, the Duke of Somerset, on the recommendation of Dr. Bryson, C.B., has appointed Dr. William Macleod to the charge of the e-establishment.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 8TH.

Dr. ALDERSON, F.R.S., President.

#### **PATHOLOGICAL AND SURGICAL OBSERVATIONS ON THE DISEASES OF THE EAR.**

(EIGHTH SERIES.)

#### **ON DISCONNEXION OF THE INCUS AND STAPES; ITS EFFECT UPON THE FUNCTION OF HEARING, AND ITS TREATMENT.**

By JOSEPH TOYNBEE, F.R.S.,

CONSULTING AURAL SURGEON TO ST. MARY'S HOSPITAL, ETC.

THE author begins by some observations on the anatomy and physiology of the chain of bones. He gives an account of the tensor tympani ligament, whereby the membrana tympani and the chain of bones are kept in a naturally resilient state. And he then shows that the function of the chain of bones is twofold: (1) to transmit sonorous vibrations from the drum to the expansions of the auditory nerve; (2) to act as the analogue of the iris in the eye by adapting the labyrinth for the reception of sonorous vibrations having varying degrees of intensity. In proof of the first-named function, the experiments of MM. Sissajous and Dessains are cited, by which faint undulating lines were produced by a slender style attached to the base of the stapes during the vibration of the drum by sonorous undulations. In proof of the second function of the drum, the fact was cited that during the act of listening the stapedius muscle relaxes the membrana tympani and the membrane of the fenestra rotunda; on the contrary, when a loud sound is expected, the tensor tympani muscle draws tense the membrana tympani and the membrane of the fenestra rotunda.

The pathological conditions alluded to in the paper are: (1) simple disconnexion of the incus and stapes; (2) disconnexion of the incus and stapes, the long process of the incus being absent.

1. The author shows that simple disconnexion of the stapes and incus, if attended with no other lesion, is not productive of any appreciable deafness, inasmuch as the tensor tympani ligament is able to keep the two bones in contact, and the action of the tympanic muscles is not interfered with. But if the membrana tympani or its ligament is relaxed, in addition to the disconnexion of the stapes and incus, then the function of hearing is interfered with, and often only to this extent, that the patient can hear only when the voluntary act of listening is performed—that is to say, when by voluntary muscular effort the incus is held in contact with the stapes. In this class of cases, gentle pressure on the outer surface of the drum by any resilient body restores the natural power of hearing, and the distress produced by the necessity of constant listening is quite overcome.

2. But if the membrana tympani or its ligament is much relaxed, then no voluntary effort can bring the stapes and incus into contact, and great deafness is the result. This deafness is also remedied by the application of an artificial membrana tympani, which, gently pressing upon the outer part of the chain of bones, keeps the incus and stapes in contact.

3. This disconnexion of the incus and stapes also occurs in conjunction with partial or complete loss of the long process of the incus, the membrana tympani being entire. The treatment in this class of cases consists in pressing inwards the membrana tympani so as to place its inner surface in contact with the head of the stapes, and to retain the two structures in contact.

The lesions above referred to also take place when the membrana tympani is perforate. When there is disconnexion of the incus and stapes, together with a thickening

of the mucous membrane or the ligaments of the articulation, the treatment consists in keeping up gentle pressure upon the outer surface of the long process of the incus; when the long process of the incus is absent, the pressure must be upon the head of the stapes. In order to exercise gentle pressure upon the ossicles and still to allow the muscles to move the ossicles, the author has recently suggested a new kind of artificial drum, in the shape of a small globe of india-rubber containing air.

Mr. HARVEY said he considered the paper of much importance and interest, inasmuch as it would show the aural surgeon the means of preventing much of the mischief this part of the organ was subjected to after long-continued and neglected catarrhal disease. He (Mr. Harvey) had paid some attention to the subject before the Society; and from the experience thus derived he was not surprised to find the incus so often the seat of mischief, and so often displaced, owing to the anatomical connexion of this bone with the mastoid cells. His own examinations had been more especially directed to the ossicles and their capsular attachments, when attacked by rheumatism, gout, and certain forms of syphilis affecting the auditory functions as a consequence, which they often seriously imperil, and it not infrequently happens that ankylosis supervenes. These lesions cannot be very accurately diagnosed at all times during life; yet he thought a sufficiently correct opinion might in many cases be made from which a rational mode of treatment could be derived, and which would be a source of gratification to the surgeon, and enable him to give much relief, and, in some cases, make a complete cure of the deafness. As regards the treatment of the cases brought forward by the author of the paper, where the incus was supposed to have been displaced, or, as suggested, dislocated from its attachments, he should like to be informed whether pressure alone had been adopted; or whether it had been combined with constitutional treatment. He thought two of the cases cited by the author pointed to such an amount of debility or relaxation of the structures as would have yielded to constitutional treatment—namely, that of giving an increased vitality to the system by tonics. The duration of time required for the cure was also a point of importance. There was another point of very grave consideration, and on which he would like to be more informed—whether the author had ever known epilepsy to have been brought into action by long-continued pressure on the ossicula; if so, he thought it would be preferable to pause rather than adopt such expedients as the author had suggested. He regretted that no history had been given of the preparations on the table by which more practical instruction would have been gained. Some useful suggestions thrown out, and many difficulties inherent in the subject-matter, might also have been cleared up.

Mr. BROOK said there was some advantage in the membrana tympani which had not been alluded to. Supposing the power of hearing to be feeble, it was possible, the membrana tympani being entire, to make the external auditory canal a reciprocating cavity by closing the external meatus. If the meatus be closed, and a tuning-fork be then applied to the head near the unclosed ear, it will be best heard by the closed one. Hence the importance of its collecting and communicating vibrations, independently of the pressure it exerts on the tympanum.

Mr. HINTON said that some cases which had come under his observation tended to support what might appear to be the weakest part of Mr. Toynbee's paper—namely, the evidence of relaxation or disconnexion of the ossicula when the membrana tympani was not perforated. In the cases referred to, of which he had seen several, the membrane was thin and relaxed, either altogether or in its posterior portion, and consequently had fallen inwards to such a degree that the head of the stapes projected beneath it. In some of these cases he had found that a stream of air passed into the tympanum, filling the cavity and raising up the membrane, considerably increasing the hearing power. But in others the opposite effect was produced: inflation

of the tympanum diminished the hearing, which was restored either by sudden strong inspiration through the nose, or by pressing in a peculiar manner upon the meatus, both of which actions had the effect of placing the membrane visibly in contact with the stapes. In some instances in which an apparently similar collapse of the membrane existed on each side, the opposite effects were produced by inflation, showing that the condition of the parts contained without the tympanic cavity was different. When drawing or forcing the membrane inwards, in the mode above described, improved the hearing, the use of the artificial membrane had frequently been beneficial.

Mr. SAVORY said the author had brought forward so much in his paper that it seemed almost ungracious to ask for more. He (Mr. Savory), however, failed to find a cause for the conditions the author described. It had occurred to him that some of the cases might have had a traumatic origin, and he asked Mr. Toynbee if this view might not throw some light on the particular way in which the disconnexion was brought about.

Mr. TOYNBEE, in reply, said that it was quite possible for the incus to be separated from the stapes as the result of a blow—indeed, one of the specimens indicated such a cause of dislocation; but, as a rule, the incus and stapes were disconnected by one of the three following causes:—(1) Relaxation of the tensor tympani ligament or of the membrana tympani itself. (2) Thickening of the tympanic mucous membrane with catarrh. (3) A loss of substance of the long process of the incus. Desirous of not encumbering the paper with pathological researches, he had deferred entering upon a consideration of the mode in which the pathological changes were effected, leaving the subject for a future paper. In reference to the difficulty of ascertaining the fact of the disconnexion of the incus and stapes when the membrana tympani is entire, Mr. Toynbee said that the affirmative could only be decided when the history, appearances, and symptoms concurred to favour the conclusion. In no case had any brain-symptoms been produced by the use of the artificial membrana tympani; indeed, it was highly improbable that the presence of the drum would produce such a result, as undue pressure on the chain of ossicles, and thence upon the vestibule, produces immediate increase of deafness. In many cases the artificial drum is dispensed with after a short time, as the chain of bones by its use appears to regain its normal resiliency; in other cases the artificial drum requires to be used at intervals. Considerable experience during many years had shown that the use of the artificial drum is attended with permanent advantage. Mr. Toynbee also said, in reply to Mr. Brook, that in the early study of the subject he had reason to believe that the artificial drum acted beneficially by constituting the tympanum a closed cavity; and he was strengthened in this opinion by the beneficial effect following the use of a bubble of mucilage for the purpose of closing the aperture. Recent researches in pathology and in operative practice had, however, induced him to adopt the conclusions cited in the paper; and he was disposed to believe that even the beneficial effect of the mucilage was due to the gentle pressure it exerted upon the chain of bones, thus conducing to render it continuous and resilient.

The PRESIDENT thought that much more would be gained by a close study of physiology as introductory to pathological investigation. He said that whilst we were fully acquainted with the mode in which light was impressed upon the retina and so communicated to the brain, notwithstanding that doubt still existed as to the true theory of the nature of light, yet, on the other hand, whilst the vibrations of the air were fully understood, very little that was positive had been ascertained as to the mode in which those vibrations were communicated to the brain.

Mr. TOYNBEE asked permission to say a few words in reply to the remarks of the President. In the first place, it was a mistake to suppose that all the ossicles could be lost without the production of deafness—the presence of

second place it was only recently that the true action of the stapedius muscle upon the stapes was made out, and the analogy of the base of the stapes to a piston and the inner surface of the fenestra ovalis to a cylinder clearly shown. And thirdly, experiments and dissections had clearly demonstrated that the action of the tensor tympani muscle was to render tense the membrane of the fenestra rotunda by exercising traction on this muscle when the scala vestibuli of the cochlea was exposed, when the fluid in the scala was seen to move outwards; and, on the contrary, when the tendon of the stapedius muscle was pressed upon, the fluid was seen to recede again.

#### A CASE IN WHICH A NEW OPERATION FOR THE RADICAL CURE OF HERNIA WAS SUCCESSFULLY PERFORMED.

By ARTHUR E. DURHAM, F.R.C.S.,

ASSISTANT-SURGEON TO, AND LECTURER ON ANATOMY AT, GUY'S HOSPITAL.

Stephen H—, a sailor, 26 years of age, sought admission to Guy's Hospital for the purpose of being radically cured of an easily-reducible but very troublesome inguino-scrotal hernia on the right side. The hernia had been first noticed six years previously. It had gradually increased in size, and extended into the scrotum. Latterly it had given rise to such constant inconvenience and so much occasional pain that the patient had been quite unable to follow his occupation. He could not wear a truss, although he had repeatedly attempted to do so. At the period of admission to the hospital the scrotal portion of the hernia was about as large as a hen's egg, or rather larger. The bowel, of which it was evident the hernia mainly consisted, was easily returned into the abdomen, but a slight fulness of the inguinal canal persistently remained.

On Jan. 19th, chloroform having been fully administered, and the hernia reduced as completely as possible, Mr. Durham proceeded to operate in the following manner:—An incision about two inches and a half in length was made through the skin and superficial fascia, in a direction at right angles to Poupart's ligament, and just over the inner border of the internal or deep abdominal ring. The tendon of the external abdominal oblique muscle was next divided in a similar direction, but to a somewhat less extent, and in a situation slightly further from the median line of the body. The lower fibres of the internal abdominal oblique or cremaster were then separated longitudinally, and the internal spermatic fascia or fascia propria of the hernia was exposed. A slight incision having been made in the lower and deeper part of this fascia, an aneurism needle was carefully insinuated through the areolar tissue, and by its means a ligature was placed between the sac of the hernia and the important structures of the spermatic cord, and carried through the upper and deeper part of the fascia. The fascia and sac were then drawn gently downwards and towards the median line of the body, and the ligature was tied tightly as high up and as far outwards as possible; in fact, as nearly as could be judged, exactly at the internal or deep ring. The ligature thus included the greater part of the circumference of the fascia propria or internal spermatic fascia just where it becomes continuous with the fascia transversalis, the whole circumference of the sac just at its junction with the general peritoneal lining of the abdominal parietes, and within the sac a small plug-like portion of omentum. In passing the aneurism needle, a slight puncture was unintentionally made into the sac. This puncture, however, when subsequently dilated, afforded the opportunity of ascertaining that the sac did not communicate with the tunica vaginalis testis, but that it contained a small piece of irreducible omentum; this was drawn out and cut off below the ligature. Finally the wound was closed above and below by sutures, which were passed through the sac. The ends of the ligature were left coming out through the middle of the wound.

The after progress of the case was most satisfactory. The patient remained absolutely in the recumbent position

for more than six weeks. From first to last he never had a single bad symptom worth mentioning. There was never any abdominal tenderness, constitutional disturbance, or other indication of general peritonitis; nor was there ever much pain about the site of the operation. The upper and lower parts of the wound healed by first intention. The ligature came away on the eighteenth day, and complete closure of the wound speedily followed. On the 29th March, the patient, having to a certain extent recovered his strength, went into the country. Before leaving the hospital he was examined by all the members of the surgical staff as well as by many visitors. There could not be discovered the slightest hernial protrusion, nor any abnormal impulse on coughing. The inguinal canal from the internal ring seemed perfectly blocked by the obliterated sac and new material.

This case, although a solitary one, may be considered to prove—first, that the method of operation described is practicable; and, secondly, that it is not necessarily attended by danger. The author would add that he believes it to be more scientific in principle than any other method yet adopted, and he hopes therefore it may prove more successful in practice.

Mr. SPENCER WELLS said that the proceeding described to the Society as *new* reminded him very strongly of operations performed centuries ago for the radical cure of reducible hernia. But, as the object of the older operators was to apply a ligature around the neck of the sac, or to obliterate it by scarification or by the introduction of foreign bodies within it, or to destroy it by caustics or the actual cautery, their proceedings proved to be so extremely dangerous, and so often unsuccessful, that when he (Mr. Wells) brought Wutzer's method before the Society in 1854 all operations for the radical cure of hernia were very generally condemned by the profession. Since 1854 Wutzer's operation had been very frequently practised here, and had often proved unsuccessful. But this was because it had been performed in cases for which it was unsuitable. Where the rings have not been much widened and the canal not much shortened it is a very successful operation, and is almost free from danger. Unfortunately, it is only applicable to a very small proportion of cases. Mr. Wood's operation is of much wider application, but it is unquestionably a more serious, not to say dangerous, proceeding. The operation performed by Mr. Durham appeared to be even more hazardous. Free division of skin, fascia, and muscle, and the application of a ligature, even if the sac were not accidentally opened, though not in this case followed by any bad symptom, might certainly be expected to lead to danger in a certain proportion of cases. And it became a grave question whether any very serious operation could be justifiable in cases of reducible hernia. If the hernia could be well supported by a truss, no operation attended with danger to life could be sanctioned. When a truss could not be borne, then Wutzer's operation in cases to which it was adapted, or Wood's operation when the rings were wide and canal short, seemed to offer at least an equal prospect of success, and to be much less hazardous than the operation performed by Mr. Durham.

Mr. HOLTHOUSE wished to know the particular reasons for performing this operation for the radical cure of hernia, and what were its advantages over other operations having a similar object. He thought Mr. Wells was in error in believing that it was the same operation which had been done some centuries ago. In the cases to which Mr. Wells referred the sac had been tied at the external ring, and thus a pouch was left open above the ligature, into which a hernia could descend. In Mr. Durham's operation the sac was tied at the internal ring. Mr. Holthouse thought the new operation was inferior to Mr. Wood's, partly because it was less safe, and partly because it dealt only with the hernial sac, and made no provision for drawing together the sides of the canal. Mr. Wood's operation, he added, blends the sac with the walls of the canal, which thus offers a firm resistance against future protrusion.

Mr. CHRISTOPHER HEATH, without wishing to detract from the credit of a successful case, could not but regard the good result in Mr. Durham's operation as in great measure due to the accidental presence of a piece of omentum within the sac, and which, therefore, served to plug the canal. This occurrence could not be looked for in every case, and even if the sac were opened, as was unintentionally done by the operator in his case, it would be scarcely possible to draw omentum down with safety. Mr. Heath thought three months too short a time to show the ultimate success of the operation, and was not surprised to hear that after the inflammation excited and the formation of an abscess there was reported to be considerable thickening of the parts. He knew from his own experience and that of others in Wood's operation that very considerable induration disappeared after a time, and he feared that then the peritoneum would again become stretched and the hernia be reproduced. Another point worthy of consideration, he thought, was the advisability of dividing the muscles to the extent recommended by the author. He feared that it would lead to permanent weakening of the abdominal parietes, as was seen after the operation for ligature of the iliac arteries.

Mr. HULKE asked if the omentum was included intentionally?

Mr. KINGDON said that it was not the fatality of former operations which had led to their disuse, as Mr. Wells had just remarked, but their inefficacy. The former, as well as the present, operations were based upon a false assumption—viz., that there was power in the adhesions thereby instituted permanently to prevent a recurrence of hernia. There was not the slightest evidence in favour of such an assumption, but the recorded evidence of Dupuytren and Scarpa was against it. Sooner or later, as Mr. Heath had stated, the adhesions were sure to yield.

Mr. DURHAM, in reply, said that although he had searched diligently he had failed to find on record the details of any such operation as was described in his paper just read. He therefore ventured to consider his method a new one. With regard to the ancient operations referred to by Mr. Spencer Wells, the descriptions given were for the most part so vague and indefinite as to afford no exact information as to the precise particulars of the methods adopted. In those instances in which the descriptions were more exact, the operations were manifestly coarse and clumsy, and necessarily involved the very sources of danger (such as sloughing of the hernial sac, wasting of the testicle, &c. &c.) which he (Mr. Durham) had been most careful to avoid. The operations most similar to his own were those of Langenbeck and Schmucker. Those surgeons, however, applied their ligature at the external, not at the internal ring. The most that could have been accomplished by such a proceeding, even if successful so far, must have been the conversion of a serotal hernia into a bubonocoele. No very great gain this. Mr. Durham had tried a new method in this case simply because it did not appear to him worth while to try either of the methods at the present time or recently in vogue—viz., Wutzer's and Wood's. Wutzer's operation had been amply proved by experience to be unsuccessful—nay, worse than unsuccessful. And, indeed, it was so unscientific in principle that the wonder was it should ever have been adopted to any extent. Mr. Wood's method was certainly very ingenious, but his own account of the results of his numerous operations did not seem to him (Mr. Durham) very encouraging. Of the sixty patients whose cases are detailed in Mr. Wood's book, between forty and fifty (a very large majority) were discharged wearing trusses, and in only six or seven of the fully-recorded cases did it appear to have been considered right to dispense with such mechanical supports. Could a hernia be said to be radically cured in the full and proper sense of the word if the patient were still obliged to wear a truss? Further, in less skilful hands than his own Mr. Wood's method had been shown to be by no means free from danger. With regard to the possible and

probable risks of his method, Mr. Durham believed that the danger of meddling with the peritonæum, particularly with such portion as forms the hernial sac, had been very greatly exaggerated. He certainly should hardly have expected Mr. Spencer Wells, of all men, to be so very fastidious and fearful about touching a little extension from that general abdominal lining which he (Mr. Spencer Wells) was in the habit of cutting into and mopping out so freely, fearlessly, and with so much impunity. The argument derived from the statistics of operations for strangulated hernia was very bad. That a large proportion of cases in which the sac was opened proved fatal was indisputably true; but the explanation was obvious. Those cases in which it was necessary to open the sac were the most dangerous, for they were those in which the strangulation was most severe or had continued longest, and, therefore, those most likely to prove fatal. There was no evidence to show that the mere opening of the sac increased the danger of the operation; indeed, in a great many cases of recovery if the sac had not been opened the hernia could not have been returned, and the patients must have died. In the present case there never was the slightest indication of any dangerous symptom whatever. There was some of the "severe inflammation," and nothing of the "extensive abscess" which Mr. Heath had suggested. In conclusion, it appeared to Mr. Durham that he had done intentionally what Mr. Wood only did accidentally—viz., close the hernial sac at the internal ring. On the other hand, Mr. Wood attempted to accomplish intentionally what he (Mr. Durham) allowed in this case to become accomplished as it might—viz., constriction of the inguinal canal and external abdominal ring. In certain cases the association of the two methods would probably be much more successful than either by itself, and such association he should without hesitation adopt.

## Reviews.

THE RESTORATIVE TREATMENT OF PNEUMONIA. By JOHN HUGHES BENNETT, M.D., F.R.S.E., &c. Edinburgh: Adam and Charles Black.

DR. BENNETT has issued this memoir with the object of inducing hospital physicians, and others who may have the opportunity, to assist him in collecting carefully-taken cases of acute pneumonia, tabulated—and we may add, for we suppose he means so—treated like his own, so as to obtain a sufficiently large body of facts to settle conclusively the proper mode of treating pneumonia. It is somewhat amusing to find that the treatment which Dr. Bennett complacently calls "Restorative" comprises a little—and sometimes not a little—of almost all those various remedies which from time immemorial have been generally employed in the treatment of pneumonia. Of the 129 cases comprised in his statistical table, nine were bled, one of them twice (3xviii. each time); five were cupped and eleven leeches; while among the pharmaceutical remedies employed we find antimony, opium, colchicum, mercury, acetate of ammonia, sweet spirits of nitre, and tincture of digitalis, either singly in separate cases, or in various combinations. It is true that nutrients were supplied in all cases according to the patients' requirements; but that has always been done—though perhaps not quite so freely—even by the greatest sticklers for the antiphlogistic regimen; it is also true that four or five out of the whole number were treated by beef-tea and wine alone; but four or five cases are far too few to found a system upon, and if the mere administration of beef-tea and wine in fitting cases and at fitting times constitutes—

as it no doubt does—a restorative treatment, wholly irrespective of what other system of medication has been previously pursued, then there was no reason for making such a work about it; for the "Restorative treatment" of pneumonia thus explained has been that practised by the best physicians in all ages.

For this treatment, this curious jumble of bloodletting and beef-tea, of wine and antimony, Dr. Bennett claims the remarkable success of only one death in 32½ for all the acute pneumonias, complicated and uncomplicated, which have been treated by him in the clinical wards, adding that of the uncomplicated pneumonias—104 in number—not one has died. To obtain these favourable results, however, Dr. Bennett has found it necessary to discard not only those four complicated cases which had the misfortune to prove fatal, but also thirteen others, which, notwithstanding the case with which he states that pneumonia can be detected and recognized, yet passed unrecognized through his wards, and were only detected in the pathological theatre (p. 22). We can hardly believe that thirteen cases of pneumonia could pass undetected through the wards of so accomplished a stethoscopist as Dr. Bennett; but it is, perhaps, better to believe such a failure in diagnosis than to suppose that a man of honour would omit recording thirteen cases of fatal pneumonia simply because they happened to militate against a favourite theory. Be that as it may, however, if we add these thirteen cases to the former four, we have a mortality of seventeen out of 142—that is 1 in 8½, or about twelve per cent.—almost precisely what he states to be the result of the last nine years' experience of the treatment of pneumonia in the Royal Infirmary of Edinburgh—viz., 1 death in 7¾ cases (p. 44). Thus we see that the results of the restorative treatment, when applied by Dr. Bennett himself, far from reducing the mortality from pneumonia to *nil*, are hardly even a shade better than the mere average results of the general treatment of the hospital to which he belongs. But as these average results include of course every case of pneumonia occurring in or brought to the hospital, we must, to make the comparison at all fair, include all Dr. Bennett's cases when investigating the ratio of mortality. Dr. Bennett, however, states (p. 29) that he has "not inserted" two or three cases brought into the house by the police in an exhausted condition, and who died before he saw them. Two or three is an indefinite number, but we may be sure they are not overstated, and if we add three to the seventeen already recorded, we have twenty deaths occurring in his wards from pneumonia alone—twenty deaths out of 145 cases, being one out of 7¼, that is a trifle above the average general mortality from pneumonia in the Edinburgh Infirmary; so that the curious jumble of treatment which he designates by the pretentious name of "The Restorative," so far from proving more favourable, is actually more fatal than what we may consider as the ordinary treatment of the present day.

Dr. Bennett's brochure is praiseworthy in so far as it is an attempt to enlist hospital physicians, and physicians generally, in the endeavour to trace out statistically the true ratio of the mortality of pneumonia to those attacked as modified by treatment. It is, however, worthy of all condemnation as a practical example of how this is to be done. To collect together a large number of cases of one disease, and, after setting aside, under one pretext or another, all the fatal cases, to claim all the recoveries as

the peculiar result of a particular line of treatment, may be well suited *ad captandum vulgus*, but is wholly unworthy of a scientific physician, and perfectly useless for the attainment of any scientific results, and it is still more useless when, as we find in Dr. Bennett's cases, even these successful cases have not been treated similarly. To claim cases of pneumonia treated by bloodletting, by antimony, and by mercury, &c., as at all upon the same footing with cases treated wholly by beef-tea and wine, merely because at some period of this course they too have had beef-tea administered, is perhaps as striking an example as could well be imagined of that "gross fallacy" which Dr. Bennett was wont to imagine to be inherent in all medical statistics, as well as a most remarkable instance of the cause of that fallacy, all the more remarkable as coming from the pen of a physician who has in former times shown himself to be such a stickler for basing statistics solely upon "individual data which are precise and equal" (*Ed. Med. Journal*, Oct. 1847, p. 308). While, even on Dr. Bennett's own showing, thirteen of his cases presented examples of that undue preponderance of opinion over fact, which he himself has instanced as one great source of the fallacious conclusions drawn from medical statistics, inasmuch as they presented—what, as pathologist to the Infirmary, he has stated that he so often found in the case of others—we do not say the absence of "the lesion entered on the tickets," but certainly the presence of "another disease which had never been suspected" (*loc. cit.*). From Bennett, the practitioner, we appeal to Bennett, the pathologist, and we ask are we not right in regarding his statistics as no better than those of his predecessors? Do not they too "exhibit to every man of common sense the gross fallacy involved in them?" (*Ed. Med. Journal*, *loc. cit.*)

### THE COLLEGE OF SURGEONS OF ENGLAND.

As time rolls on, and each successive year brings round the anniversary when the Fellows of the College of Surgeons of England are called upon to exercise their privilege of electing Councillors, the constitution of the College is brought more and more prominently under the notice of the profession, its defects are presented in a broader light, and its improvement is more palpably suggested and more imperatively demanded. Under the system of government which prevailed in the College at the commencement of the present century no beneficial change could have been reasonably anticipated, but under the recent charters the constituency has gained so much power, that with judicious management such a lever might be applied as would effectually remove many of the obstructions which now impede the liberal members of the Council in their efforts at reform. Unfortunately the College has fallen into a vicious career, from which it can be diverted only by the combined operation of time and of extraneous influences. From

persons in possession of power and place, it is almost hopeless to expect any change in a system by which they themselves live and thrive, and it can only be by the application of external pressure that new ideas can be introduced or new blood infused.

The constitution of the Court of Examiners, as it at present exists, is essentially faulty, and while the self-election of the same Examiners is entirely indefensible upon any grounds of fairness or expediency, their constant re-election by the Council is hardly less to be reprobated: yet we find that year after year the same Examiners are elected, although in the majority of cases the Council has the power of appointing new ones at annual or quinquennial periods. The result of the present system is, as every body knows, to perpetuate in a very important and responsible office a set of men who, however able and competent they may have been in former years, are now for the most part past the age when their functions can be exercised with credit to themselves or advantage to the College. Another patent defect in the constitution of this body is that while the Examiners are nominally elected by the Council, they themselves constitute a very considerable part of that Council, and therefore in a certain sense they elect themselves. The non-election of Mr. CÆSAR HAWKINS some year or two since, to the Council, has broken in to a limited extent upon the old and faulty system, and that gentleman, although still holding his seat at the Board of Examiners, has no longer a vote for his own election. In the forthcoming election in July, if it should happen that Mr. LUKE is not re-elected, then two members of the Court of Examiners will be no longer members of the Council, and eventually the desirable consummation may be brought about of separating altogether the Council from the Court of Examiners.

There can be no doubt of the necessity and propriety of such a movement, for the Council can never exercise an independent choice in the election of Examiners so long as the latter hold seats at the Council Board. It is also in every way expedient and desirable that the position of Examiners should not be held by persons of an advanced age, but by persons in the prime of life, well acquainted with all the recent views in pathology and surgery, and well able to devote a sufficient time to the careful scrutiny of the claims of the candidates for the diploma.

We are told in the reports on the Visitation of Examinations presented to the Medical Council at its last meeting, that the examination of candidates for the diploma of the College of Surgeons of England is a moderately good one, so far as it goes, but this last sentence modifies very much the previous commendation, for a testimonial granted by the College, and qualifying a man to practise surgery, and being moreover the only qualification possessed by hundreds of the profession, ought to be a thoroughly trustworthy document indicating that the possessor has not only received a competent professional education but has passed through an efficient

examination. Now the ordeal can hardly be called efficient when its range comprises only anatomy and surgery, virtually if not actually excluding physiology, and actually excluding all such collateral subjects as chemistry and materia medica. Nor can the examination be very searching when we are told that the oral part of it in the anatomical subjects lasts only twenty minutes, and we believe that in the surgical part the oral examination lasts only about an hour at the utmost.

Now we cannot help thinking that without unduly trenching upon the domain of other examining bodies, the College of Surgeons might demand from its candidates some knowledge of at least the elements of chemistry and materia medica, and we are disposed to agree with the visitors in their suggestion that some means might be taken to test the candidates practically in the duties of surgery, such as in the application of bandages, splints, &c., and in passing the catheter and in performing other operations. We fear that there is too much truth in the impression which generally prevails, that of all the examining bodies, the College of Surgeons of England (if not the most lenient) is one of the most lenient to its candidates, and that even in the restricted field to which its examinations are limited, the requirements are not of a very high order. Thus it happens that candidates who would have no chance of passing at other examining Boards, often find but little difficulty at the College, and many, when they have once secured its diploma, enter immediately into practice, without even aiming at the acquisition of any other qualification.

We cannot but believe that these defects in the system of examination at the College are in great measure due to the circumstances that the Examiners are elected over and again almost as a mere matter of routine, that they are handsomely, too handsomely remunerated, and that they are in general too much advanced in years, and some of them too much engrossed with practice, to devote adequate time and attention to the examinations. We see very little chance of reform until the Council is altogether independent of the Examiners, the Examiners are paid a fixed salary, are really removed from office from time to time, and are inelegible after a certain age.

THE observations which we thought it necessary to make respecting the accusations of plagiarism of the *Lancet* against Dr. FOSTER of Birmingham, in respect of his pamphlet on the sphygmograph, have not elicited any editorial explanation from that journal. In its columns appear a note from Dr. ANSTIE, whose name we quoted in connexion with the matter, in which that gentleman very temperately disclaims any of the merit due to its introduction into English medical practice. In our observations we stated that Dr. FOSTER's pulse-traces "have never been anticipated," and as this is not strictly accurate, we take the earliest opportunity of correcting it. The fact is, that all the pulse-traces in Dr. FOSTER's paper were taken from cases under his own observation, but they confirm what M. MAREY has himself observed, and the results which he obtained by artificially reproducing th

conditions characteristic of the various valvular diseases of the heart. This misconception, however, cannot in any respect, affect our unqualified condemnation of the course taken by the *Lancet*, which, being a simple statement of facts, admits of nothing but simple retraction or refutation. As our contemporary is unable to supply the latter, and unwilling to concede the former, it rests with the profession to assess the damages.

#### THE AUSTRIAN MEDICAL SERVICE.

THE following information reached us on the authority of "An Old Subscriber" too late for us to verify its accuracy:—

The Austrian Government are in urgent need of Medical Officers. Assistant-Surgeons are paid on entry seven florins (fourteen shillings) per day, with the rank of Lieutenant, and after probation of Captain, full Surgeon ranks as Major.

After the war the medical officer may either retire on a bonus or accept a permanent appointment as vacancies occur.

In addition to this pay all rations are found.

The pay and rank of the Naval Service is the same as the Army.

#### THE MEDICAL ACT.

THE following petition was presented by Colonel North, M.P. for Oxfordshire, on the 7th inst:—

*To the Honourable the House of Commons in Parliament assembled.*

We, the undersigned qualified practitioners residing and practising in the town of Banbury and its neighbourhood, were by an Act, 2nd August, 1858, required to register under such Act; and upon producing our certificates we, upon a payment of money, were registered accordingly.

Now we complain that by an informality of this Act it is totally inoperative, inasmuch as, by a legal difficulty in the clause No. 40, an unregistered person practising here is allowed to assume a title to which we hold he has no right, inasmuch as the Medical Council under your Act have totally ignored and refused to register it.

Also, seeing that your honourable House is about to pass an Act to prevent unlicensed veterinary surgeons—that is, those who treat the complaints and, as now, preside over the lives of the brute creation—from practising their art without due examination and proper licence, and supposing that the lives of her Majesty's subjects may be held of equal value and entitled to the same protection, we, in our humble capacity, can but urge it as a fair supposition that, in your legislative wisdom, you will so far amend the present Medical Act of 2nd August, 1858, as to afford to those practitioners qualified under it that protection which they have expected by a registration under its requirements, which it was no doubt intended to supply, but which from its imperfect construction it has hitherto so signally failed to effect.

And your petitioners will ever pray.

(Signed)

Banbury; Richard Grimby, M.R.C.S., Banbury; W. W. Hyde, M.R.C.S., Bloxham; John Colegrave, M.R.C.S., Bloxham; J. MacGreal, M.R.C.S., Alkerton; W. T. Douglas, M.R.C.S., Banbury; R. S. Wise, M.D., Banbury; George Fayrer, M.D., Henley in Arden; Thomas Clarke, M.R.C.S., Banbury.

THE Birkenhead Commissioners have agreed to advertise for plans for the erection of public baths and the necessary amount of land, at a cost of £8000.

PETITION FROM THE COW-KEEPERS OF LONDON ON DISINFECTANTS.

WE publish below a petition which has been presented to Parliament by Mr. AYRTON from the cow-keepers of the metropolis and others, praying for a scientific inquiry on disinfectants in connexion with the cattle plague. It will be seen that the allegations made in the petition reveal a state of things in respect to the way in which the subject has hitherto been treated by the Royal Commission which appears to be anything but satisfactory. It seems remarkable that with so great an array to choose from of eminent chemists, many of whom are possessed of medical qualifications and practical knowledge of epidemics, the Cattle Plague Commission should have employed to report on disinfectants—a medico-chemical question—a non-medical gentleman, and that they should have made choice of one who is the inventor and co-patentee of a disinfecting compound. If the Commission had from the first made up their minds to recommend carbolic acid and sulphur fumes as the best disinfectants, they could hardly have taken a more effectual way of securing such a consummation than by handing over the inquiry to one who holds a patent for a disinfecting powder, the only active ingredients of which are carbolic and sulphurous acids. Any one in the chemical world on learning that Dr. R. ANGUS SMITH had been charged with the duty of reporting on disinfectants, must have perceived that those two substances would be recommended. It is true that the last report in their favour was drawn up by Mr. W. CROOKES, but that gentleman was named at the suggestion of Dr. R. ANGUS SMITH.

An admirable opportunity of elucidating by extensive experiments the nature of infection and the practical operation of disinfectants, we fear, has been lost. To judge from the reports on disinfection which have been issued, we should say that few or no experiments, except laboratory, ones have been made, either by Dr. SMITH or Mr. CROOKES. In the last report an ingenious theory of the nature of the rinderpest virus has been set up by the latter gentleman—namely, that it consists of “vital organised septic cells or germs” (of which vaccine lymph is the type), “which feed on some of the elements of the blood, and at the same time secrete a poison to which the symptoms of the disease may be immediately due.” But not a single fact is given as the bases of this somewhat complex theory. Yet it is in virtue of these speculations that Mr. CROOKES apparently distrusts the efficacy of oxidizing disinfectants, and relies instead on the antiseptics of the ancients, sulphur fumes and the tar acids.

“THE HUMBLE PETITION OF THE UNDERSIGNED COW-KEEPERS OF THE METROPOLIS, AND OTHERS,

“SHEWETH,—That your petitioners have with the utmost regret and disappointment observed that the Royal Commission which was appointed to inquire into the nature of, and the best way of combating, the cattle plague at present raging in this country, while fully recognizing the highly infectious character of the pestilence, have adopted very inadequate measures for the discovery of the most efficient means of disinfection.

“That your petitioners have been surprised to see that instead of advising on the subject of the choice of disinfectants with chemists of the first rank, to whom no improper bias could possibly be imputed, the Cattle Plague Commission devolved that part of their duty to Robert Angus Smith, Esq., of Manchester, Doctor of Philosophy, who is co-patentee with one McDougal of a disinfecting article known and sold under the name of McDougal’s powder.

“That your petitioners have noticed with pain to have

taken place that which they think ought not—namely, that under the advice of the gentleman in question, the Commission in the report which they published on the 15th of February last, recommended the very article of which Messrs. Smith and McDougal are patentees, in the following words—viz. :—‘The experiments of Dr. Angus Smith show that the best disinfectants are carbolic acid, or McDougal powder, and chloride of lime.’

“That, besides having reason to deplore the suspicion which has thus been cast on the recommendation of the Commission, relative to disinfectants, independently of the merits or otherwise of the substance or substances recommended, your petitioners consider their cause of complaint is much increased by the circumstance that the substance put forward as the best disinfectant in their report—namely, ‘Carbolic Acid, or McDougal’s Powder,’ is one which all standard works on chemistry (except ‘Ure’s Dictionary,’ the article on disinfectants contained in which was written by the said Dr. Angus Smith), and all the most competent chemical authorities have classed among antiseptic, or preservative agents, as distinguished from true disinfectants.

“That your petitioners have reason to believe that the experiments stated in the Report of the Cattle Plague Commission to have been made on the subject of disinfectants by the said Angus Smith, who has been shown to be co-patentee of McDougal’s powder, were conducted in private on a totally inadequate scale, and under the influence of a strong bias in favour of that article.

“That your petitioners having from the first outbreak of the cattle plague made use of a system of disinfection not recommended, nor even alluded to, by the Cattle Plague Commission in their above-named report, by means of which their loss of cows in their district having been very limited in number, they are firmly convinced that the system in question, and adopted by them, is well calculated to combat and arrest the pestilence.

“That your petitioners would here take leave to quote the report of Dr. Barclay, Medical Officer of Health of the parish of St. Luke, Chelsea, at the last meeting of the vestry upon the subject of disinfectants, as evidence of a scientific and important character, in support of the article known as Condry’s Fluid, and the one which your petitioners have had in use, and referred to in this petition, as follows:—

“A suggestion which has been made by your Inspector seems to me well worthy of your consideration. In the course of examining cowsheds which have been attacked by the cattle plague, he has been instructed to urge on the cow-keepers the importance of using disinfecting agents, and he has found that Condry’s disinfectant fluid has more effectually than any other removed any noxious smells arising from the decomposition of animal and vegetable substances. He has consequently been led to test its effect on public places, and believes that it might be economically as well as usefully employed. I can of my own knowledge well bear out his testimony to its special powers in arresting certain forms of chemical decomposition.”

“That your petitioners being of opinion, from a consideration of the above circumstances, that the Cattle Plague Commission have treated in an inadequate and unsatisfactory manner that part of the trust confided to them relative to disinfectants, and being at the same time deeply impressed with the vast importance of proper disinfecting measures, which in fact constitute the complement to all other precautions against the spread of the cattle plague, humbly pray that your honourable House would in your wisdom order a full and impartial inquiry by chemists of the first rank, and other competent but unprejudiced persons, on the subject of disinfectants, in order that the public by their unbiased conclusions may be saved the loss and disappointment which cannot fail to result from agents which are inefficient, illusory, and dangerous.

“And your petitioners will ever pray, &c.

“EALAND ALDER. “THOMAS CROSS.  
“CHARLES MAY. &c. &c. &c.”

THE mortality of the metropolis continues to be greatly beyond the ordinary average. In the week ended Saturday, June 9, the number of deaths was 1313, the average of the ten previous weeks being 1087. Measles, scarlatina, whooping-cough, typhus, and diarrhoea continue to be unusually fatal. Four fatal carriage accidents in the street are registered, and three deaths from cholera.

PROCEEDINGS OF MEDICAL COUNCIL, MAY 25.

RETURNS OF EXAMINATIONS FROM THE ARMY MEDICAL DEPARTMENT.

Statement of the Degrees, Diplomas, and Licences of the Candidates for Commissions in the Medical Department of the Army, who during the year 1865 have presented themselves for Examination, showing the number that passed, and did not pass, distinguishing the Qualifications, both Medical and Surgical, under the heads of the several Licensing Bodies.

J. M. GIBSON, Director-General

REPORT OF THE FINANCE COMMITTEE.

The following Report of the Finance Committee was received, and ordered to be entered on the Minutes:—

The Finance Committee beg leave to present, in the table

subjoined, a statement of the estimated and actual income and expenditure of the year 1865; also an estimate of the income from ordinary sources, and of the expenditure, as far as the Committee are able to judge, for the year 1866.

## Parliamentary Intelligence.

### HOUSE OF COMMONS.

JUNE 11TH.

#### STRAND UNION WORKHOUSE.

Sir J. SIMEON asked the President of the Poor-law Board whether the inquiry into the treatment of the sick poor in the Strand Union Workhouse was completed, and whether he would lay a copy of the evidence and the report founded thereon upon the table of the House.

Lord ENFIELD replied that the inquiry had been completed, and that he expected to be able to lay the evidence on the table in the course of a few days.

#### THE CATTLE PLAGUE.

In answer to a question by Sir J. C. JERVOISE as to the prevalence of pleuro-pneumonia amongst cattle, as stated in the Cattle Plague Commissioners' Report,

Mr. BRUCE said the powers of the Privy Council were founded on the 11th Victoria, as amended by the Act of this session, and these powers had been hitherto held to apply to the sudden outbreak of cattle plague, and not to chronic disease. It might be doubted whether under the power of these Acts, the Privy Council had the power to order the killing of animals suffering from the disease to which he supposed the question referred.

#### THE CHOLERA CONFERENCE.

Sir J. C. JERVOISE asked the Under Secretary of State for Foreign Affairs what progress towards a settlement of the question had been made since the objection was taken by the English, Russian, Turkish, and Persian representatives at the Cholera Conference, Constantinople, to the proposal of the French representative for the stoppage of all sea communication between Arabia and Egypt, and for the presence of several vessels of war in the Red Sea in case of another epidemic?

Mr. LAYARD replied that a conference proposed by the representatives of nearly all the European nations had assembled at Constantinople to take into consideration the spread of cholera from the East. The conference had come to certain resolutions, and when they were reduced to a convention, her Majesty's Government would consider them, and see how far they could adopt the recommendations of the conference, and what steps could be taken to carry them out.

JUNE 14TH.

#### METROPOLITAN WORKHOUSES.

Colonel HOGG asked the President of the Poor-law Board whether he would lay the report of Mr. Farnall and Dr. Smith on the state of the metropolitan workhouses, when complete, upon the table of the House.

Lord ENFIELD said that one of the reports, that of Mr. Farnall, was already completed; as soon as the other was completed and read they should both be laid on the table of the House.

#### ARMY AND NAVY MEDICAL OFFICERS.

Colonel NORTH asked the Secretary to the Treasury whether the recommendations of the committee presided over by Admiral Sir Alex. Milne, relative to the medical officers of the navy and army, and upon which the authorities both of the navy and army had been for some time in communication with the Treasury, were likely to be decided upon shortly. He begged to remind the House that the committee reported early in February.

Mr. CHILDERS—In reply to my hon. friend, I have to state that the circumstances are these:—In July last the College of Physicians wrote to the War Office complaining that the status of army surgeons was unsatisfactory, and to the Admiralty that navy surgeons were both, as to pay and rank, not on a par with army surgeons. In consequence, the War Office and the Admiralty appointed a Department Committee, consisting of military and naval officers, and of medical men recommended by the Colleges of Physicians and Surgeons to inquire into the rank, pay, and position of the surgeons of the two services. The Treasury were not parties to the inquiry, and they have as yet only been officially in communication with the Admiralty on the subject. When we are in possession of the definite views of both the departments we shall be in a condition to deal with the cases of both the army and navy surgeons at the same time. The question is a very important one, involves a large amount of money, and requires careful consideration.

Colonel NORTH asked whether no communication had been received from the War Office.

Mr. CHILDERS said the War Department had not yet made their recommendations upon the report of the committee; but he personally had been in communication with his noble friend.

### REJECTED CANDIDATES.

THE importance of the brief reply given by Mr. Baring in the House of Commons on Monday night to the question put by Sir John Hay as to the present dearth of surgeons for the navy, has probably made little impression on more than the few persons who know what underlies that brief official statement. In effect, he said, that only three surgeons had been obtained for the service this year, and that there was difficulty in obtaining any. There was some hitch in carrying out the recommendations of the recent committee on the rank and pay of medical officers of the army and navy, owing chiefly to obstacles raised by the Treasury. We may supplement this information by adding that at the last examination there were three candidates, who had to be all rejected, and it is understood that there are seventy vacancies. In order fully to appreciate the plight to which our sailors are likely to come unless the present state of things be mended, we will quote from some recent returns which we published as having been furnished by the Director-General of the Medical Department of the Navy to the General Medical Council which recently held its annual session at the College of Physicians in Pall-mall. These returns are of great public interest, although more instructive than reassuring. They show the number of candidates examined for commissions as assistant-surgeons in the navy during the year 1865 and the results of their examinations. During that year twenty-one candidates in all presented themselves for about three times that number of appointments. Of these four had been previously rejected, and one underwent two examinations in the twelve months, having been unsuccessful on the first occasion. Of these twenty-one candidates, nine had to be totally rejected, and of the twelve successful candidates, five passed "indifferent" examinations, two "moderately good," and five "good" examinations. The majority of those rejected were utterly ignorant of Latin, which is the language of prescriptions, two are marked as so ignorant of materia medica that it would have been dangerous to have admitted them, two failed altogether in anatomy and surgery, and some were pronounced deficient in every important branch of medical knowledge.

When these returns came under the consideration last week of the eminent medical men representing the different medical bodies in the United Kingdom, they necessarily became the subject of comment, and it was explained what all this meant. The great resource of the medical departments of the public services of late years has been found in the Irish schools.

Mr. Hargrave, President of the Dublin College of Surgeons, said that it would be most unfair to suppose that these candidates were at all a fair sample of Irish medical students so far as their attainments were concerned, any more than the English candidates were representative of the average attainments of English medical students. It was well known that no young medical man of good birth or education would submit to enter the naval service under the present conditions. "There would be dross in every society or institution, and no doubt among medical men. There were some who were ignorant of Latin and Greek, and even of English, and such were the men who were likely to enter the navy, which was rapidly reverting to the state of things existing in the time of Roderick Random."

Dr. Stokes, the Regius Professor of Medicine in Dublin, confirmed this statement, declaring that such was the indisposition among the better class of medical students to enter the army and the navy, that the sweepings of the class of medical students presented themselves for examination

before those boards, although the case was worse for the navy than for the army. The Director-General of the Army, who is much more reticent of information, has declined this year to furnish the desired information; but as that service is in much the same disfavour as it was last year, we may conclude that the information then supplied fairly represents the present state of things.

Dr. Parkes then laid before the Council some specimens of the replies of the rejected candidates, which are extremely edifying, and some of them as humorous as anything Horace Smith ever wrote. For instance, one gentleman who wished to take the lives and health of soldiers under his charge did not know the big bone of the arm from the little one when both were shown him; another replied in writing to the question, what would he do if he had to treat a wounded bloodvessel, that he would immediately amputate the limb above the injury. That there might be no mistake as to these facts, the manuscripts were handed to the Council. Another man, who had been two years at a London school and one year at a Scotch school of medicine, had never heard that the term scabies is applied to a disease called the itch. Another divided foods into nitrogenous, such as all vegetables, and non-nitrogenous, all meats, including carnivora, sub-divided into albuminous, such as hens' eggs; fibrous, such as the meat of the ox or sheep; caseous milk and cheese; and gaseous, soda-water. No wonder that Mr. Paget, after carefully testing such men to see what they did know, hopelessly characterize them, in terms of medical diagnosis, as "dull all over;" although, had the answers been intended as jokes, they would have been entitled to rank as really clever. The serious conclusion from all this is, that our soldiers and sailors are entitled to claim that any reasonable means which have been declared after due inquiry well fitted to restore confidence in the medical services of the army and navy, and to restore their faded popularity, shall be taken without delay.

The blue-book containing the evidence taken before the committee of inquiry to which we have referred and the recommendations of that committee has not, we believe, been issued to the House or made generally known. In fact, Lord Hartington seemed disposed lately in the House of Commons to rebuke a military member for referring to what the Marquis described as a confidential document. It is difficult to say why it should be considered confidential, and we are very glad to see that the Admiralty at least, although so poorly backed by the War Office, is disposed to urge the fulfilment of these recommendations.—*Pall-mall Gazette.*

#### RATING OF HOSPITALS.

THIS question has become one of vital importance to every hospital in the kingdom. Hitherto, acting under decisions of Lord Mansfield and Lord Kenyon, parishes have not rated hospitals; but a decision of the House of Lords last year upset the previous decisions. The result is, that all the London parishes have set to work to assess the different hospitals in the metropolis; and, in doing so, have acted in a most absurd and contradictory manner. They have, in fact, been guided by a mere rule of thumb.

For instance, Paddington has, we understand, rated St. Mary's Hospital at £100 *per annum*; whilst St. Marylebone has rated Queen Charlotte's Lying-in Hospital, a very much smaller establishment in the same neighbourhood, at a like sum. The Westminster Hospital again, has been assessed at much less than either of the above. But, perhaps the most extraordinary instance of perverted ingenuity has been shown in the case of St. George's Hospital. St. George's, Hanover Square, the richest parish—at least it must contain a larger number of rich people than any parish in the world—has rated the hospital at upwards of £4000 a-year. On this rating the governors will have to pay just about £600 a-year. £600 to be paid to the parish for doing day by day parish work.—*Brit. Med. Jour.*

## Correspondence.

### POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your allowing me, through the medium of your journal, to inform the Poor-law Medical Officers, and I may say, the profession generally—for it concerns all—that the Vaccination Bill has passed through the Select Committee, and is again before the House of Commons.

In my communications to the Select Committee I suggested alterations in the title and preamble and in nineteen clauses, or proposed to substitute nine new clauses. On examining the bill, I find the title and preamble still stand without Wales being mentioned, but twenty-three clauses have been altered verbally and otherwise, and one Clause (5) added. The four forms in the schedule have also verbal alterations. Allow me to here state, however, that all my suggestions have not been adopted.

With due appreciation of the value of the efforts made by the meeting held at the Freemasons' Tavern on April 10, and by private individuals, still it appears to me that the efforts made by the Poor-law Medical Reform Association have had considerable influence—first, in actually stopping the bill when about to go into committee of the House of Commons by means of a pamphlet forwarded to each member and by private communications; and secondly, by suggestions made to the Select Committee itself. But that influence could never have been made to bear, had not money been subscribed to pay the expenses of printing, &c.

I have no hesitation in saying that the amendments now proposed in the Vaccination Bill will amply repay the members of the Poor-law Medical Reform Association in a pecuniary point of view, for all the money they have subscribed during the last ten years; and I hope will stimulate the entire body of Poor-law Medical Officers to subscribe to the funds of the Association, in order to enable it to prosecute with vigour the changes sought in the general administration of the medical relief of the poor. The seed has been sown; the eyes of the public have been opened; a large portion of the members of the House of Commons now listen to us; and the time cannot be far distant when very considerable changes must be made in the medical relief of the poor.

Clauses 5 and 6 in the amended Vaccination Bill (quoted below) will show the pecuniary changes proposed. On and after January, 1867, the public vaccinators are to receive not less than 1s. 6d. for each successful primary vaccination performed in a workhouse. This is a gain, as at present no fee is legally payable. The 1s. 6d. fee now paid for vaccinations performed at a station within one mile of the residence of the medical officer, is not increased, but 6d. is added to each fee for all vaccinations performed at a station over one mile, and under two miles distant, thus making the fee 2s. Beyond two miles, the fee, which is now 2s. 6d., is to be not less than 3s. In addition to these payments, it is proposed by Clause 5 to pay 1s. extra for each child whom the vaccinator has successfully vaccinated; but that will depend on the "number and quality" of the vaccinations on the "Reports" made to the Lords of Her Majesty's Council and the time to which the award relates.

This clause is ambiguous, but on enquiry I find the payment is intended to depend upon the manner in which the vaccination is carried out—that is, if done in accordance with the approval of the inspector. My correspondent says, "If you glance at any of the inspectors' reports you will see on what system they go in judging the vaccination of a place, and by their reports the medical officer of the Privy Council would be guided to recommend the payments in question."

They would be additional payments, made on the principle of payment for results. I hope it will be of general benefit to the public vaccinator whose interests will be identical with those of the public." The re-vaccination of those previously successfully vaccinated will be under special arrangements, and only paid for at two-thirds of the fee of successful primary vaccination.

I regret we have not obtained more; but if we do our duty well, and Clause 5 be fairly carried out, the bill will be a gain to us of some thousands per annum, and I feel sure will place the public vaccination of this country on a more satisfactory footing. That the bill might have been more efficiently amended cannot admit of a doubt; but official influence was too strong for us, and a satirical print (worth looking at) by Standidge and Co., forwarded to me by a member of the Select Committee, representing the poor-law vaccinators receiving £200,000 per annum—the registrars £20,000—Simon, Bruce, and Co., £10,000 a year, &c., had its weight in preventing our receiving that redress which we desired.

I have again addressed the Poor-law Board, asking that a deputation of Poor-law Medical Officers may be permitted to wait upon them on July 5th, which I trust may be granted.—I am, &c.,

RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, June 9, 1866.

Clause 5.—On reports made to the Lords of Her Majesty's Council with regard to the number and quality of the vaccinations performed in the several vaccination districts of England, or any of them, the said Lords may from time to time out of monies provided by Parliament, and under regulations to be approved by the Lords Commissioners of Her Majesty's Treasury, authorize to be paid to any public vaccinators, in addition to the payments received by them from guardians or overseers, gratuities not exceeding in any case the rate of one shilling for each child whom the vaccinator has successfully vaccinated during the time to which the award of the said Lords of the Council relates.

Clause 6.—Every such contract for vaccination shall provide for payment in respect only of the successful vaccination of persons, and, so that the rate of payment for primary vaccination shall be not less than the following: that is to say, for every such vaccination done at an appointed station situated at or within one mile from the residence of the vaccinator, or in the workhouse of the union or parish, not less than one shilling and sixpence; and for every such vaccination done at any station over one mile and under two miles distant from his residence, not less than two shillings; and for every such vaccination done at any station over two miles distant from his residence, not less than three shillings; such distance being measured according to the nearest public carriage road.

### INDIAN MEDICAL SERVICES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The extract from the *Delhi Gazette* will show the systematic manner in which the local Government out here ignore any warrants which tend to benefit the regular Indian Medical Services. But this does not surprise any one who understands matters and sees the heads of our department quite easy on the subject, and perfectly indifferent as to how their juniors are treated.—I remain yours, &c.,

VERITAS.

In our issue of 5th of April was inserted a letter from our London correspondent, noting amongst other things the recommendations of the commission to inquire into the condition of the Medical Officers of the Army and Navy, and we are glad to see that these recommendations all tend in the right direction. One cause, however, of the dislike to the army medical department among the *élite* of our young me-

dical men, seems to have been entirely overlooked—namely, that every one entering the department may reasonably expect to spend a large portion of his service in India, the local government of which has for years past systematically ignored medical warrants wherever these warrants conferred any benefits upon the medical department. The pay of relative rank was for years withheld from medical officers in the British army, and until a year ago it was no uncommon thing to find an Assistant-Surgeon who had followed the fortunes of his regiment throughout the Crimean war and the mutiny campaign, in receipt of the beggarly pay of Rs. 286-10, and this after eight, nine, or ten years' service. The student looking around for a career, naturally inquires, "What guarantee have I that this or a similar contravention of fair promising warrants may not occur again?" and to decide him he finds that the medical department specially subordinate to the Indian government, is in a state of collapse and depression piteous to behold, and that no efforts have been spared on the part of the local government to insult and degrade its medical officers. He finds that some 150 Assistant-Surgeons in the Indian service are retained by force in civil employments, upon salaries a quarter or a third less than those laid down in a new warrant recently issued for that service, and the suggestive fact that now that their pay happens to be more than the pay of their relative rank, a curiously devised, and more curiously interpreted resolution, orders that when a civil medical officer resigns his appointment, because his pay is less than the new military pay, he is, if the local government cannot dispense with his services, to be paid, not the pay he would get with a regiment, but the bare pay of a military officer of the same relative rank. Hearing this discussed in all its bearings, it is not to be expected that our student will trust himself to the tender mercies of the Indian government.

There is only one way in which this chronic and well-founded distrust can be removed—viz., that distinct rules be laid down as to pay, rank, &c., in the different stations occupied by the British army, not to be upon any pretext meddled with by the local governments, except through the ordinary military and civil tribunals. This last effort on the part of the Indian government for foiling the well-meant efforts of her Majesty's ministers to make the military medical service popular, has been most successful. Not only has it saved the State some £30,000 and deprived some 150 gentlemen of annual sums of from £100 to £250—a highly satisfactory stroke of policy, but it promises to bring about, that there shall be soon no medical officers at all to pay, whereby a large saving will be effected, and funds will be set free for purposes of native female education in the Punjab, or for the purchase of screw piles for the ornamental works in the course of erection at Mutlah, or other useful and necessary purposes.

The question of the supply of army surgeons is one of great and increasing consequence, and it is not to be endured that the little meannesses and class prejudices of Bengal civilianism, should aggravate the difficulties, already great, of obtaining that supply.

### ON LABOURERS' DWELLINGS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have just read in your issue of the 30th ult. the able paper by Dr. Mapother "On Laborers' Dwellings," and am sure it cannot fail to be as instructive as it is interesting. As an example of a town overcrowded by the reception of vagrants at night, Dr. Mapother quotes Swords. I feel it is due to Swords, or at least to one of its many proprietors, to state that within some few years past there have been built by an encouraging landlord (Mr. Baker of Balhearg) a lot of laborers' cottages in a part of the town, healthful by pure air and good sewerage. Those cottages, which, I need not observe, are never untenanted, afford to the occupants of them the greatest comfort, by their well-ventilated *multum in parvo* rooms, their neatly arranged yards—in fine, by their general construction. I mention this that Dr. Mapother may understand that Swords is, I am happy to say, not retrograding, and it is to be presumed that the inhabitants of those cottages, having deserted comparatively unwholesome dwellings, thereby afforded a greater amount

of accommodation for vagrants than they hitherto could have obtained.

If the landlords of those laborers' cottages in Chapelizod, Carrick-on-Suir, Ennis, and the other towns to which Dr. Mapother alludes, would only visit Swords, and inspect those nice little cottages to which I refer, I am sure they would see the utility as well as the humanity of erecting similar ones, instead of the hovels graphically described by Dr. Mapother. I am sure there could be no better movement, or one attended with more beneficial results, than the adoption of a weekly or bi-weekly inspection of the lodging-houses and dwellings of the poor, if such could check the overcrowding of those houses, especially in the harvest season, when hundreds of laborers, tempted by the high rate of wages, congregate in this and other small towns, and it becomes a mystery to know how or where they can make off sufficient space in any of the then very crowded houses by which to rest their wearied bodies.—I am, Sir, your obedient servant,

F. J. DAVYS, A.B., M.D.

Swords, June 1, 1866.

#### GRIFFIN TESTIMONIAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In consequence of the paucity of my answers in favour thereof, the committee of the above fund has given up the idea of a banquet to Mr. Griffin. As, doubtless, the College election will bring some medical men to London, it is intended to make the presentation of the testimonial on July 5th prox., unless the Poor-law Board should fix some other day to receive Mr. Griffin's deputation. In this latter case the testimonial will be given him immediately after the interview with the President. The time and place will be duly notified by printed circular. The testimonial is now on view at the manufacturers, Messrs. Mappin and Webb, 71 and 72, Cornhill. Intending subscribers, who have not forwarded me either their subscriptions or their *cartes de visite* will obligingly do so without delay.—Yours obediently,

ROBERT FOWLER, M.D., Treas. and Hon. Sec.

145, Bishopsgate-street, Without, June 13, 1866.

#### THE VACCINATION BILL.

To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled.

The petition of the undersigned, on behalf of the Manchester Medico-Ethical Association,

HUMBLY SHEWETH,—That it is of great national importance that universal and compulsory vaccination shall be established by law.

That a Bill is now before your honourable House which has for its object the attainment of this end.

That the Bill, while highly commendable in its ultimate aim, is defective or erroneous on the following points:—

1. That no public prosecutor of persons evading its enactments is provided for, without whom it is likely to become almost a dead letter.

2. That the rate of remuneration awarded to the public vaccinator is insufficient, more especially as it affects the country medical practitioners.

3. That the compulsory demand (enforced by penalties) from all medical practitioners of professional service to the State without remuneration, is an oppression of one class of the community for the benefit of the rest, and contrary to the whole spirit of British legislation.

4. That no adequate provision is made for a sufficient and periodical supply of vaccine lymph from the cow.

Your petitioners, therefore, humbly pray that your honourable House will pass such a measure as will secure this country from the ravages of so dreadful a malady as small-pox, and that the four points above-named may at the same time obtain your earnest consideration.

And your petitioners will ever pray.

Signed on behalf of the Manchester Medico-Ethical Association,

J. THORBURN, M.D.  
J. WILSON, F.R.C.S. } Hon. Secs.

#### BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-fourth Annual Meeting of the British Medical Association will be held at Chester, on Tuesday, Wednesday, Thursday, and Friday, the 7th, 8th, 9th, and 10th days of August next.

President—S. J. JEAFFRESON, M.D. Cantab.

President-elect—EDWARD WATERS, M.D. Edin.

The Address in Medicine will be delivered by J. HUGHES BENNETT, M.D., F.R.S. Edin., Professor of the Institutes of Medicine and Clinical Medicine in the University of Edinburgh.

The Address in Surgery will be delivered by WILLIAM BOWMAN, Esq., F.R.S. etc.

The following special subjects will be introduced for discussion:—

Dr. SIBSON, F.R.S., and Mr. HOLMES: What is the influence of Hospitals on Health and Mortality?

Dr. STEWART: Is the Expectant Method to be relied upon in the Treatment of any form of Acute Disease?

Mr. ALFRED BAKER (Birmingham): Are there any trustworthy facts as to the Origin of Pyæmia?

PROFESSOR CHRISTISON, F.R.S. (Edinburgh): Observations on the Register of Deaths in Scotland.

T. WATKIN WILLIAMS, *General Secretary.*

13, Newhall Street, Birmingham, June 5th, 1866.

#### DEATH OF MR. ALEXANDER URE.

WE regret to announce the death of Mr. Alexander Ure, surgeon of St. Mary's Hospital, while yet in the prime of life. Until lately he was a man of uncommon vigour and personal activity. But three years ago he met with a heavy fall from a horse, while attending in the field as surgeon to the Scottish volunteers, and from that time he began rapidly to decline. He was a man of genial nature and upright and honourable character. As a surgeon he was distinguished by his care and success in the after treatment of his patients subsequent to operation. He had a rare knowledge of the chemical and therapeutical departments of materia medica, and possessed a large store of professional erudition, with which he was very ready in clinical teaching. He will be much regretted by a large circle of friends.—*Lancet.*

#### CERTIFYING SURGEON AT BATLEY.

IN the House of Commons, on Monday, Mr. F. Beaumont asked why the appointment of certifying surgeon under the Factory Acts for the Batley district, vacant on the 16th day of April, was delayed by the inspector for a period of three weeks, and then filled by the nomination of a non-resident stranger, without regard to the wishes of the mill-owners and manufacturers of the district? Sir G. Grey said the appointment of certifying surgeon under the Factory Acts was placed by law in the hands of the inspector, and not of the Secretary of State. Upon inquiry, he had ascertained that the delay was occasioned by a doubt entertained in the first instance whether any fresh appointment was necessary, or whether there might not be a redistribution of offices. The gentleman, selected from among nine or ten candidates, had been a certifying surgeon in another district, and might therefore be considered experienced in the discharge of his duty. If any dissatisfaction were felt with his decisions, power existed to call in another opinion; but in no case had this been done.

THE Registrar-General of Scotland reports that in the month of May there were registered 2518 deaths, a larger number than any recorded in the last ten years, and 353 above the average. This great excess was caused by an increase of the deaths from ordinary diseases, more especially from those affecting the respiratory organs. Forty per cent. of all the deaths were of children under five years.

## Our Weekly Retrospect of the Medical Journals.

JUNE 16TH.

THE *Medical Times and Gazette* in a leader refutes Dr. Johnson's new theory and treatment of cholera, especially as regards the utility of opium, which has been so decried by those who follow the doctrine lately enunciated.

Attention is drawn to the subject of the formation of local museums, as recommended by Mr. Toynbee, and lately carried out in the neighbourhood of Wimbledon. The scheme, if successful, would tend greatly to educate the rustic mind in a scientific direction, so that hereafter from such a small beginning much good might be expected.

Again there seems some doubt as to the carrying out by the War Office of the recommendations of the Committee which lately sat to take into consideration the rank and pay of the army and navy medical officers. It is to be remembered that the Commander-in-Chief is the most violent opponent of the scheme in question.

A very good description is given of the properties and preparation of nitro-glycerine, which some short time since caused such consternation in San Francisco by the explosion of a vessel which contained some of this substance among the cargo.

Our contemporary wonders how such an excellent medical officer as Dr. Rogers could have been induced to continue to hold office under such masters as the guardians of the Strand Union, who "sanctioned and supported a system of neglect and cruelty."

The secretary of the fund for defraying the legal expenses of the Messrs. Armstrong in the late trial, has issued a circular to the effect that no further subscriptions are required.

Ovariectomy has been successfully performed in New Zealand by Dr. Mackinnon, an army surgeon.

Dr. Jago of Plymouth publishes a correspondence between himself and an insurance company; it exhibits a very reprehensible system of touting for business. The company promise to appoint a medical gentleman their local referee and to publish his name as such, provided he insures in the company to the amount of £600, at the same time offering the same terms to other medical men in the neighbourhood.

Dr. Lionel Beale contributes a paper on Vital Force, in reply to Mr. Moxon.

Mr. Hulke relates several cases of night blindness, particularly among sailors.

A case of strumous meningitis is related from St. George's Hospital, in which tetanoid spasms occurred; they were controlled by the application of ice along the spine, although the patient ultimately died. It would be well to recollect this plan of treatment.

The *Lancet* resumes its analysis of Dr. Bennett's paper on "Medical Education;" it draws attention to the useless habit of demonstrators in the dissecting-room giving long-winded orations, in place of going about from table to table to question the student and help him individually in his studies.

Again the approaching election for the Council of the College of Surgeons is discussed. Mr. Luke is objected to, as "he combines in his own person all the monopolies. Twice President, seventeen years a Councillor and Examiner in perpetuity, he seeks to renew his hold upon a seat at the Council board."

The Canadian Medical Council has held its first sitting, which was enlivened by a discussion as to the admission of a Mr. Campbell, a homœopathic practitioner, to a seat at the Council. He was finally rejected by a majority of nine to seven. A very excellent plan is that by which the members of this Council are elected as the representatives of districts, so that the body contains men who are quite independent of the schools and individual interests.

The hospital board of Hartlepool think that they can get as house-surgeon "a very clever" man for £80 a year

and board, to see patients, to dispense medicines, and to be Dr. Moore's assistant in private practice during spare hours, Dr. Moore to pay part of the salary. We do not know whether the latter is a consenting party to the arrangement. A Liverpool coalheaver can get five shillings a day now, and from eightpence to one and fourpence per hour for every hour he works over-time. This would be preferable to the pittance enjoyed by curates in the Church and assistants in the medical profession.

There is to be an exhibition of pharmaceutical matters at Nottingham, in connexion with the Pharmaceutical Conference to be held there at the same time as the meeting of the British Association.

The cholera is showing itself everywhere.

Mr. H. Smith alludes to the treatment of gonorrhœa by soluble bougies made of cocoa butter containing those salts which are generally used in the cure of the disease.

Thirty candidates for the Indian Medical Service are required on the 6th of August.

Professor Hancock's lectures on the Anatomy and Surgery of the Foot are continued.

Dr. Anstie's Lettsomian Lectures on Certain Painful Affections of the Fifth Nerve are commenced. He has had a good opportunity of studying neuralgia and its sequelæ and complications in his own person.

Mr. H. Thompson describes a new instrument for the treatment of severe stricture of the urethra. His principle is to over distend and not to rupture, as in Mr. Holt's method. This he manages by a screw, which gradually opens the blades of the instrument. He alludes to the anatomical fact that the portion of the urethra usually the seat of stricture is in its natural state of a calibre at least double that of the orifice.

Dr. Sanders records a case of loss of speech, with right hemiplegia depending on lesion of the left island of Keil and neighbouring convolutions. Within the last year very many similar cases have been recorded, bearing out the theory of Broca as to the localisation of the faculty of speech.

From the *British Medical Journal* we learn that the House of Lords has upset the decision, formerly acted on, of Lords Mansfield and Kenyon, and that as a sequence the London parishes have commenced to rate the various metropolitan hospitals. St. George's is put down as valued at £4,000, for which the guardians have to pay £600 a year.

Dr. Lankester is taken to task for affirming that the prediction of Dr. Farre as to the dying out of the cattle plague has been almost literally fulfilled, thus ignoring the Privy Council and its mandates.

There is a translation of an excellent paper by Dr. Max Hertz, of the Foundling Hospital, Vienna, on the gangrene of infantile life.

Drs. Johnson, Skinner, Spitta, Noble, and Greenhow have letters on the treatment of cholera.

### SERIOUS CHARGES AGAINST A SURGEON.

AT the Farnham Police Court, on Tuesday last, Lake Young, *alias* William Augustus Young, was brought up on remand before F. R. Thresher, Esq., and Major Spring, charged with embezzlement, felony, and obtaining goods under false pretences. It appeared from the evidence of Dr. W. Davies, of York Town, Frimley, with whom the prisoner had recently been engaged, that in the month of April last the prisoner obtained his situation as assistant, upon what afterwards proved to be misrepresentations and a false certificate. A month's probation was mutually agreed upon, and it was the duty of the prisoner to attend patients and dispense medicine. At the expiration of the month, however, the prisoner was discharged, but for what cause did not appear. Shortly after his leaving the situation it was discovered that an entry had been made in the day-book of medicine supplied to a tradesman near Sandhurst, which, it afterwards transpired, had been paid for, and not accounted for by the prisoner, by whom the entry

was made. Suspicion led to further inquiry, and it was then ascertained that several things belonging to the surgery were missing, including a caustic pencil-case, and several medical works, among them being Dr. Ferguson on "Surgical Treatment," Hutchinson on "Cases of Emergency," Tanner's "Practice of Medicine," etc. It was also found that the prisoner obtained wearing apparel and other goods from the tradespeople to a considerable amount, by means of false pretences, one of which was that he was engaged permanently as a medical practitioner, and was desirous of opening accounts. On his asserting that he had entered into an agreement to remain with Dr. Davies for one year, he succeeded in obtaining a handsome watch, value ten guineas, from Mr. Porter, jeweller, Hartley Wintney, to whom he also stated that he had a daughter about to be married, and that he should therefore become an extensive purchaser. The police were subsequently communicated with, and it was found that he had succeeded in obtaining a fresh situation, under an assumed name, as assistant-surgeon to Dr. T. L. Hales Smith, of Fetter-lane, Fleet-street, London, where he was apprehended by Sergeant Hyde, of the Surrey constabulary. Search was made in the prisoner's rooms, and several pawnbroker's duplicates were found, one of which was for the watch in question. The officer then produced a list of the articles missing from Dr. Davies' surgery, and on allusion being made to the caustic pencil-case, Dr. Smith at once stated that it was presented to him by the prisoner shortly after his engagement. The prisoner cross-examined the several witnesses with all the ingenuity and skill of a barrister, but did not succeed in shaking their testimony. The prisoner in defence admitted having given the caustic pencil-case to Dr. Smith, but emphatically denied taking it from Dr. Davies' surgery with any felonious intent. He also stated that it belonged to the old stock of the Orphanage Asylum, Frimley, of which establishment Dr. Davies was medical officer, that he had used it in the profession generally, but did not attach any particular value to it. He was formally remanded for the completion of depositions, when he will be committed to take his trial on the above-mentioned charges. The prisoner wept bitterly on being removed to his cell.

## THE QUEEN'S UNIVERSITY IN IRELAND, DUBLIN CASTLE.

### First Examination in Medicine.

June 11, 1866.—Morning.

#### MATERIA MEDICA AND PHARMACY.

EXAMINER.—DR. W. D. MOORE.

1. Write an unabbreviated prescription, in Latin, for pectoral pills of squill, ipecacuanha, and opium, with directions for use, for an adult.
2. What is scammony? Into what officinal preparations does it enter? and what is the form for preparing the *mistura scammonii* of the British Pharmacopœia?
3. What is the strength of the morphia suppositories of the British Pharmacopœia?
4. Mention the Linnæan class and order, the natural family, and the generic characters of the scammony plant.
5. Write an unabbreviated prescription, in Latin, for powders of chalk and Dover's powder, for a child of a year old, with directions for use.
6. What is elaterium? What are its medical properties? and in what doses would you prescribe it?
7. How is precipitated sulphur prepared?
8. What is saffron? Mention the Linnæan class and order, and the natural family of the plant producing it.
9. What is the strength of the "Vinum antimoniales"? In what doses would you prescribe it, and for what purposes?
10. How is the *Vinum Ferri* prepared?

#### Examination for the Degree of M.D. or M.C.H.

MEDICAL JURISPRUDENCE.—EXAMINER.—DR. W. D. MOORE.

1. What is the usual post-mortem appearance of the

mucous membrane of the tongue, mouth, and throat after poisoning by oxalic acid?

2. What is the smallest quantity of oxalic acid which has been known to destroy life, and what is the largest quantity recorded after the ingestion of which recovery has taken place?

3. What are the ordinary post-mortem appearances in a case of poisoning by strychnia?

4. What are the best tests of the presence of prussic acid? Describe the modes of applying them and their effects.

5. What is the smallest fatal dose of essential oil of bitter almonds on record?

6. A method of detecting chloroform in the blood and tissues in cases in which it has proved fatal in the form of vapour, has been founded on the effect of a red heat in resolving its vapour: what are the principal products of this action?

7. What is the difference in the effect of heat upon the sublimate of metallic mercury and that of arsenic?

8. What are the symptoms of chronic poisoning by lead?

9. What limitation in time does the law assign to the occurrence of death after the infliction of a wound, beyond which the charge of homicide will not be tenable? Is the limitation correct in principle?

10. How does corrosive sublimate, as a poison, differ in its effects from arsenic?

SURGERY.—EXAMINER.—ROBERT McDONNELL, M.D., F.R.S., F.R.C.S.I.

1. Describe the disease known as "Chronic mammary tumour" and its diagnostic characteristics.

2. What are the symptoms which in your opinion call for the application of the trephine in injuries of the head?

3. Describe a case of simple onychia, and its treatment.

4. A patient has been suffering from strangulated hernia for some hours: what means will you have recourse to try to effect its reduction before proceeding to operation?

5. Describe the mode of arresting hæmorrhage by acupuncture.

6. What are the symptoms of *morbus coxæ* in the first stage?

MIDWIFERY AND DISEASES OF WOMEN.—EXAMINER.—LOMBE ATTHILL, M.D.

1. In which of its diameters does the fœtal head most usually enter the brim of the pelvis? and describe the changes which take place in its position during its descent through and expulsion from the pelvis.

2. Enumerate the causes which may occasion delay in the second stage of labour.

3. What are the conditions which should be present, to render the use of the forceps likely to be successful, and what precautions would you adopt before applying them.

4. How would you treat a case of "Partial Placenta Prævia," the os being the size of a shilling, and the patient losing a good deal of blood?

5. In twin cases a considerable interval sometimes occurs after the birth of the first child. How long would you wait, supposing no urgent symptom were present, before you interfered? And what means would you finally adopt with the view of terminating the labour.

6. With what other presentations are you liable to confound that of the face? What special diagnostic mark enables you to distinguish it from any other presentation? And why are cases of face presentations generally tedious.

7. How would you treat a case of amenorrhœa occurring in a young woman, who also complained of debility, loss of appetite, and pain in the back, and who suffered from habitual constipation?

~~~~~  
BROMATE OF QUININE—A NEW REMEDY.—M. Courtener, a Russian physician, recommends the bromate of quinine as a new and useful remedy applicable to intermittents and some other diseases, such as dysentery, typhoid fever, and diphtheria. It has a sedative action superior to the sulphate of quinine, and therefore may be given in smaller doses. M. Courtener considers 50 centigrammes a sufficient dose. It is quite soluble, one part being dissolved in four parts of water, a property which adapts it for hypodermic injections. The use of it is rarely followed by tinnitus aurium. This medicine is prepared by treating quinine with hydrobromic acid and then evaporating to crystallization or dryness. M. Courtener recommends it as a prophylactic of cholera, and in its period of incubation.—*Bulletin Gén. Therapeutique.*

Abstracts of the Scientific Societies.

ARCHÆOLOGICAL INSTITUTE.—Mr. J. Beldam contributed a paper, "On the Icenhilde and Erming-street Roads."—Mr. J. H. Parker gave a discourse on the Primitive Fortifications of Rome. From many passages in classical authors it is evident that the original settlement was on the Palatine, and that this was surrounded by cliff, slope, and foss from the beginning; the foss marked out by the plough with oxen being one of the earliest incidents in the history of Rome. To this original city on the Palatine the Capitol was speedily added, as the *arx*, or citadel, more strongly fortified than the rest, as was usual, having been in this case a natural rock, called the Tarpeian Rock, which none of the other hills were; all the others had the cliffs *scarped*, that is, cut by the hand of man, and the earth must always have been supported in a vertical position by artificial means, originally by boarding, and, as the boards decayed, by stone walls. There are remains of walls of the time of the Kings of Rome on each of the seven hills, and in other parts, walls of the time of the Republic and of the Emperors, sometimes built upon or against the walls of the Kings. The roads at the low level, at the bottom of the *fosse*, called covered ways, became the streets of the city, and their level was not altered until the time of the Empire, when the alteration began for convenience, and has been going on ever since. The market-places, or *fora*, were at the same level as these original streets. All early cities consist of three parts—the *arx*, or citadel, the town, and the pasture-ground. In Rome, accordingly, there was originally the Capitol for *arx*, the Palatine for town, and the Aventine for pasture-ground. The *arx* had a triple line of fortification, the town a double one, and the pasture-ground a single one only. The lecture was illustrated by an archaeological plan of Rome, and by a number of photographs of the objects mentioned. The great point which the lecturer aimed to bring out was, that all these early remains confirm in a remarkable manner the early history of Rome according to the first book of Livy, which it is the fashion to call a myth.—Mr. E. A. Freeman, who bore testimony to the value of Mr. Parker's inquiries, disputed some of his inferences. He thought it hardly possible to recover the real history of those early times to which allusion had been made. Many of the expressions of Livy were obviously full of suggestion, and doubtless many historical facts may be gleaned from that historian's early books, as they may also from Homer; but he thought that the day had gone by for Pliny to be implicitly relied on. We know all the records of Rome were destroyed on the occasion of the invasion of the city by the Gauls.—Mr. J. G. Waller described the curious inscription on Cowling Castle, in Kent. It is a very fine specimen of enamelled work, perhaps a unique example of such work employed in the open air. The inscription, which Mr. Waller, in company with Mr. Roach Smith, was enabled closely to examine in the autumn of 1864, represents a parchment deed, with its appendant seal. The material is copper, and the inscription consists of twelve plates, each line consisting of three. The white enamel is still in very fair preservation, and the colour, both of the shield of arms and of the cordon by which it is attached, which are the heraldic colours of the arms of Cobham, are generally preserved. The third Lord of Cobham, who erected Cowling Castle, is said to have placed the inscription on the face of the castle, and Mr. Waller believed the tradition to be correct.—Dr. Kendrick of Warrington, exhibited a remarkably fine series of casts of the Imperial Golden Bullæ, commencing from the thirteenth century, and ending with Leopold the Second (1790-92). The obverse and reverse were in each case represented.—Earl Dunraven exhibited and described three very curious silver dishes, found close to the Abbey of Tore, in the county of Westmeath, under seven feet of turf. They belong to Dr. Stokes of Dublin. Dr. Rock thought they were

for domestic use, and probably Irish work of the thirteenth century.—Mr. S. Dodd exhibited a MS. Bible and a MS. Testament, both of the fourteenth century, and on fine vellum.—The Rev. E. G. Jarvis sent two curious horse-bits, of iron, one of them found in Lincolnshire.—Col. Tempest brought a painting which formerly had belonged to Sir Richard Phillips, and is mentioned in one of his works. The portrait has been engraved as that of Chaucer; but the Society were of opinion that there was no ground for supposing that it was intended to be a portrait of the author of the "Canterbury Tales."—A curious prize race-whip, of silver, 1790, was exhibited by Mr. O. Morgan, M.P.; a Roman denarius of Domitian, in excellent preservation, was shown by Sir J. C. Jervoise, Bart., M.P., by whom it was found in Hants; and a fine jacinth intaglia, archaic Greek, representing the head of Sappho, was contributed by the Rev. Gregory Rhodes. This gem was formerly in the Mertens-Schaafhausen collection, and is said, by the learned author of "Antique Gems" (Mr. King), to be the most ancient intaglio head that has come under his notice.

ROYAL INSTITUTION.—"On Mud Volcanoes of the Crimea, and on the Relation of these and similar Phenomena to Deposits of Petroleum," by Prof. D. T. Ansted, M.A.—The special thanks of the members were returned to Sir H. Holland, Bart., for his eighth annual donation of £40 to "The Donation Fund for the Promotion of Experimental Researches."

SOETY OF ARTS.—May 30.—The paper read was, "On some Popular Errors concerning Australia," by the Hon. C. G. Duffy.

PECULIAR PROPERTIES OF ACETATE OF SODA.

A "HISTORY of Acetate of Soda," has been published in which some curious physical and allotropic properties of this substance are detailed. We have not yet had an opportunity of seeing the paper, but M. Legrand in *Union Méd.* gives a brief account of some of its contents. From this it appears that crystallised acetate of soda melts in its water of crystallisation at a temperature of +58 Centigrade, and when it is exposed to cold, after being dissolved, it crystallises at this temperature, which remains stationary during the whole time that the crystallisation continues, so that acetate of soda in crystallising presents a fixed point at 58° C., just as water, in the crystallised state, presents in melting a fixed point at 0° C. Dissolved acetate of soda which is exposed to cold but secluded from the air, either in a vessel that is corked or one that is simply covered over, does not crystallise; but what is in the highest degree surprising is that, while cooling thus protected from the air without crystallising, it retains in a latent condition the greatest portion of the caloric which it had absorbed when entering into a state of solution. This caloric reappears and is disengaged when the crystallisation of the salt is induced by simply exposing the solution to the air on uncorking or uncovering the vessel which contains it.

This singular property leads to a curious result. The temperature of 60° C. is easily obtainable from the sun's rays concentrated under a glass frame, and therefore the solar heat suffices for the solution of acetate of soda. But if this solution be effected in a corked or covered vessel, it will retain the greater portion of the caloric absorbed, and will restore this when convenient on the vessel being opened. And the quantity of caloric so absorbed is considerable, for 1 kilogramme of the acetate melted and cooled down to 0° C. will disengage, on removing the crystalline condition, sufficient caloric to melt 360 grammes of ice or raise 360 grammes of water from 0° C. to 79° C.

"In fine, here is a means of magazing solar heat. What will come of it in practice? Will human industry be able some time hence to store up for winter a provision of caloric which has been collected during summer? Why not? The observations of M. Jeannel are, as it were, the first steps on this seemingly fantastic path."

THE Marquis of Westminster has given £500 towards the endowment fund of Yeatman Hospital, at Sherborne, in Dorsetshire.

CASE OF POISONING BY NARCOTIC VAPOURS IN A DISUSED TAR-BOILER.

MR. NOWELL supplies the notes of a case of singular interest, under the care of Dr. Gull, at Guy's Hospital :

T. L.—, aged forty-two, a labourer, was admitted Feb. 20th, 1866. He was employed at a gas-tar distillery, where pitch is made. One of the large boilers or stills, which are eight feet deep, and connected to one another by short pipes, capable of being opened or shut off by taps, was undergoing repair, and had been empty for more than a week. The engineer had been down on the 16th ult., without suffering any inconvenience from the gases generated in the adjoining still, and had gone down again on this day at eight a.m. to repair the damage. Whilst thus engaged he called out, and the present patient going to see what was wanted observed him reclining on his arm, like one dead or asleep. Whilst going down a ladder to his assistance, he in his turn suddenly called out for some one to steady the ladder, and would have fallen but for help. He was dragged out insensible and continued so for more than an hour. Then he became quite ungovernable, and endeavoured to bite and strike any one who came within his reach, requiring three or four men to hold him. He made a great outcry, and from the description given would appear to have resembled a person affected with epileptic mania. Three hours afterwards he was admitted into the hospital, and the following note was then taken of his condition:—"He will be quite still if not disturbed; but when moved or touched cries out, and requires to be restrained. He is not conscious of surrounding objects; his pupils are dilated; common sensation is not impaired. The breath is rather cool, skin moist, and he is perspiring freely; legs and feet cool; shivers now and again. Respirations easy, not stertorous, 20 to the minute; pulse 50, regular, very weak. Half an hour afterwards he could swallow fluids freely; his eyelids were firmly closed, and sensibility to cold is noted as being increased. He endeavours to wrap the clothes more closely around him. He will not answer when spoken to: pulse 64; respirations 20, quiet. In half an hour's time he was conscious of surrounding objects, looking wildly and astonished; could talk distinctly and rationally; pulse 72, rather full; respirations 24; skin moist. His urine contained a trace of sugar. The man told the reporter on the following day that he had no recollection of anything which occurred after his descent into the boiler until he found himself in bed next morning."—*Lancet*.

[From the suddenness of the insensibility in this case, the character of the sleep, the dilatation of pupils, the epileptiform paroxysms, the comparative quiet of the pulse and respiration, and from the fact that the urine contained sugar, we infer that this was a case of poisoning from the inhalation of carbonic oxide gas. The symptoms are identical with those we have observed in inferior animals after their exposure to carbonic oxide.—*Brit. and For. Med. Rev.*]

NON-INTERVENTION IN EMERGENCIES.

A CORRESPONDENT of the *Times* animadverts upon the etiquette—law he hopes it is not—"which forbids any chemist to leave his shop, even to render assistance in the most urgent cases where a doctor's services cannot be obtained at a moment's notice." Referring to a sudden seizure of illness which terminated in the death of a lady, he says—"In the case to which I have alluded, no professional aid could be procured until too late to be available, although four medical men were summoned as early as possible. Two chemists in Oxford-street refused to do more than send for a doctor, notwithstanding they were informed of the pressing need of instant succour. Those around the unfortunate lady did all in their power in the hope of restoring her to consciousness but unprofessional efforts must be uncertain and often misguided. It is the profession and business of a chemist and druggist to make and sell medicines, not to practise physic. He must needs know how to prepare sal-volatile, and he may have lancets to vend, but he may not know the difference between coma and syncope, and whether a person in a fit requires bleeding or a stimulant. He would render assistance at the peril of the patient, and also at his own. He has before his eyes the possibility of making a fatal mistake, and the

horrible fear of a trial in a felon's dock, resulting, at the least, in ruinous law expenses consequent on a verdict of manslaughter, returned against him by a British jury, under the direction of a British coroner. 'Enforce responsibility,' that is a British maxim. Its necessary correlative, unfortunately, is 'Run no risk.'"

PRE-HISTORIC MAN.

IN the autumn of last year, an order to erect a viaduct across the Derwent Valley near Malton, the North-Eastern Railway Company commenced the formation of cofferdams on each side of the river. In the first formed, on the Malton side, as reported at the time, after ten-feet of the fluviatile post-tertiary clay had been excavated, a three feet bed of alluvial silt was entered, which abounded with water, and caused the cofferdam to burst. Beneath this sand was the Kimmeridge clay of the Vale of Pickering, and upon it, at a depth of thirteen feet, the femoral and pelvic bones of a human being were thrown out, the skull then being left within the piles forming the dam. An enlarged dam having been formed, operations were re-commenced last week, when the skull so much desired was fortunately obtained, and is now deposited in the collection of pre-historic *crania* of the Rev. William Greenwell, of Durham. The bones, from long steeping, have become blackened and devoid of lime, resembling leather more than bone, and are much impregnated with vivianite. The body has been that of a male of small stature apparently from 40 to 45 years of age. The teeth have all been present, and are not much worn, but the sagittal suture of the skull is almost obliterated, and so is the coronal suture. It has been supposed that the body was one of an early British race, but the skull is not at all typical, and not in the least like those obtained from either the long or the round barrows of the Britons. It is very broad in the occipital region, and rather narrow in the frontal; but the main characteristic is flatness. Mr. Greenwell says the skull is very like some he has from a Kentish Roman cemetery, but is relatively broader in the occipital region. He can offer no conjecture as to race, but supposes the man may have been a dependent on the Romano-British camp at Malton, probably an auxiliary. This view is strengthened by the finding, in another excavation, but on the opposite side of the river, and also below the clay and silt, a rudely-formed vessel, upturned. This is about six inches high, and is regularly hand-made, entirely without ornament, but is not like British ware at all. The material is more like the ordinary bluish Roman pottery, and is hard-baked, but there is neither the form nor finish of Roman ware, nor any trace of the potter's wheel. The shape is that of the "food-vessel," and if Romano-British is extremely rude indeed. Up to the present time no further object has been found. The skeleton and the pot seem to have reference to the same date, being both found at the same depth (10ft. clay and 3ft. silt), both also being below the bed of the river Derwent considerably. During the human period there has been considerable alteration in the geological deposits on the surface, as was recently illustrated by the section of the cutting for the Norton drainage close by, where an ancient (supposed) British trackway was found beneath water-borne sand and gravel. Mr. Greenwell, Captain Copperthwaite, and other antiquaries and geologists, consider that the skeleton and urn mark the level of the British period, and that the super-imposed beds have been left by the river accumulations since that period. A look-out is being kept for any object likely to give further light.

It appears that the terrible compound, nitro-glycerin, may be rendered non-explosive by a method comparable with Mr. Gale's method of protecting gunpowder. According to the *Mining Journal*, the recent accidents with the new explosive agent have induced Mr. Nobel to turn his attention seriously to the subject, and he is now enabled to state that by mixing the nitro-glycerin with methylic alcohol, it is rendered unexplosive, either by percussion or heat. When required for use water is added, which absorbs the spirit, and the oil sinks to the bottom of the vessel, whence it is drawn by a syphon. It is stated that experiments for testing the value of this discovery have already been made in America, and have given highly satisfactory results.

Notices to Correspondents.

Mr. T. J. E. Browne, Waddesdon.—We have not yet received the pamphlet.

Mr. Griffin.—The letter is inserted.

A Subscriber.—The communication has been received.

Tyro.—There is no antidote, properly so called, for the poison in question.

Dr. M.—A new edition of the book is now in preparation.

J. S., Liverpool.—We have already stated our opinion that the castor-oil treatment of cholera is objectionable, whatever theoretical reasons may be given for its use in this disease.

Dr. B.—We have not yet received the paper alluded to by our Correspondent.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College, having undergone the necessary examinations for the Fellows ip on the 29th and 30th ult., were reported to have acquitted themselves to the satisfaction of the Court of Examiners, and at a meeting of the Council on the 14th inst. were enrolled Fellows of the College:—

Archer, Edmond, Cape of Good Hope; diploma of membership dated Dec. 29, 1866.

Bruce, Alexander, Albert-terrace; April 26, 1864.

Darling, William, New York; Nov. 21, 1856.

Duka, Theodore, H. M. Indian Army; Oct. 7, 1853.

Falwasser, Francis, Army; March 28, 1855.

Jordan, Thomas Furneaux, Birmingham; May 2, 1854.

Little, Louis Stronnyer, Broomfield-st., Grosvenor-sq.; April 22, 1862.

Lush, W. N. Geo. Vawley, Wilton, near Salisbury; April 27, 1864.

Marsh, Fred. Howard, St. Barthol. Hospital; June 1, 1863.

It is stated that only one candidate failed to acquit himself to the satisfaction of the Court.

APOTHECARIES' HALL OF LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on June 7th:—

Braunson, Henry John, Scarborough.

Brownbridge, Dixon Snaith, Yorkshire.

Colquhoun, Frederic Stuart, Tiverton, Devon.

Haswell, Narcis Richard, Helston, Cornwall.

James, John Rees, Llanelly, Carmarthenshire.

Leverson, Edward James, Truro, Cornwall.

The following gentlemen also on the same day passed their first examination:—

Giles, John, St. Bartholomew's Hospital.

Lewis, William Bevan, Guy's Hospital.

Moore, George, General Hospital, Birmingham.

Nutt, Charles, Guy's Hospital.

Stokell, George, Guy's Hospital.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The following Candidates passed their examination as Pharmaceutical Chemists:—

Baker, Parson Custance, Holt.

Day, John, Retford.

Davies, J. H., Newcastle-on-Tyne

Goucher, John, Wellington Salop

Pasnia, Thorny, Mauritius.

Horner, Thomas B., Woolwich.

Thorn, John James, Crediton.

Averill, Henry A., Stafford.

Baxter, George, Chester.

Long, John F., Bristol.

Pheysey, Richard, Waterloo.

The cholera still rages in Holland. In Rotterdam last week there were eighty-five cases, fifty-five of which were fatal.

QUARANTINE.—A Gibraltar telegram of the 12th inst. states that the Board of Health has imposed five days' quarantine on vessels from all English ports. The Government has, at the solicitation of the local authorities, directed that H.M.S. *Eolus* shall be stationed in the Southampton Water as a receiving ship, should necessity arise, for the prevention of the introduction of cholera cases into the port.

MARRIAGE OF THE PRINCESS MARY.—The representative of medicine at the marriage of Princess Mary was Dr. Quin.

DEATH FROM CHLOROFORM.—A few days since, says the *Boston Medical Journal*, "another victim to this murderous anæsthetic died in a dentist's chair in the city of Philadelphia."

JAMAICA HOSPITAL.—The appointment of a medical man from Montserrat to the chief surgery of the hospital in Jamaica, has caused great annoyance in the medical pro-

fession. A remonstrance has been addressed to the Colonial Secretary on the subject.

PUBLIC HEALTH.—The Government Bill upon this subject now before the House of Commons contains some clauses that should be generally known. A penalty not exceeding £5 is imposed for exposure in any public place or public conveyance of any person suffering from a dangerous infectious disorder without proper precaution against spreading it; and there is a like penalty on the owner or driver of a public conveyance who does not immediately provide for its disinfection after it has with his knowledge conveyed any such sufferer. Carriages for the conveyance of such persons may be provided by the local authorities. The sewer authorities may compel the owner of any house in their district which is without effectual drainage to remedy that defect. Various other powers are given by the Bill to the sanitary authorities for the sake of the public health.—*Times*.

THE PRUSSIAN ARMY.—The cholera has made its appearance at Altenburg, and this town is not far from the right flank of the Prussian army. All precautions are being taken against it, and the medical officers will not be found sleeping at their posts. Austrian deserters declare that typhus has already laid a heavy hand upon the Kaiser's troops. From the Prussian lines one thousand sick soldiers have already been sent to Berlin.

PROSECUTIONS UNDER THE RECENT REGISTRATION ACT.—At the last Carlow Petty Sessions District two parties were summoned by D. Shewbridge J. Connor, Registrar of Births, Marriages, and Deaths for the Carlow district, for failing to comply with the requirements of the Act. One of the persons was charged with neglecting to register a death, and the other for an incorrect registry of birth. On behalf of defendants it was contended that the summonses were informal, inasmuch as the Act was silent as to the person in whose name the summonses in such cases should be brought, and did not empower the Registrar to proceed for the penalties. At the suggestion of counsel for the defence, their worships decided upon submitting the case to the law adviser of the Crown for his opinion, and the cases were accordingly adjourned pending his decision.

WORKHOUSE INFIRMARIES OF LONDON.—The *Times* states that the Association for the Improvement of London Workhouse Infirmaries have forwarded, by the hand of the Earl of Carnarvon, to the President of the Poor-law Board, the statement of alleged neglect, cruelty, and inefficiency in the treatment of the sick in a west-end workhouse infirmary. The statement is made by a paid head nurse who was there but a short time, but who has had considerable hospital experience, and whose testimonials are excellent. The house referred to is Paddington Workhouse. She describes instances of gross neglect and particular acts of great cruelty committed by pauper nurses. The nursing would seem to be most inefficient, and classification of patients to be ignored. The children are spoken of as especially ill-treated, and the general picture drawn is, in its way, as discreditable as that which proved to be a true account of the Strand Infirmary by Miss Beeton. The committee ask for an immediate official inquiry, as the facts alleged are of quite recent date. It is one of the greater importance because the Paddington Union is one of the very wealthiest in London, and with a very small number of poor; and the guardians have always maintained a high reputation for humanity and good management; so much so that when the Archbishop of York in warmly protesting, at the meeting at Willis's Rooms, against the general inefficiency of the arrangements made by the various boards of guardians for the sick poor of London, he especially named, among those who were entitled to be excepted, the Paddington guardians, having heard a very good report of their house from a source which he considered authentic.

UNIVERSITY OF OXFORD.—In Convocation, on the 13th instant, the honorary degree of D.C.L. was conferred on Sir J. Y. Simpson, M.D., F.R.S.E., of Edinburgh; Alphonse de Condollo, corresponding member of the French Academy of Sciences; Joseph Dalton Hooker, M.D., F.R.S., Director of the Royal Gardens at Kew; William Thomson, M.A., F.R.S., Professor of Natural Philosophy, Glasgow; James Prescott Joule, F.R.S.; John Phillips, F.R.S., M.A., President of the British Association for the advancement of Science.

Vacancies.

Herts County Hospital—House-Surg. con and Secretary.
 Royal Portsmouth and Gosport Hospital—Assistant House-Surgeon.
 South Staffordshire General Hospital—Surgeon, vice Mr. F. A. Nesbitt, deceased.
 St. Matthew, Bethnal-green (No. 4 District)—Medical Officer and Vaccinator.
 Tisbury Union (Bonhead District)—Medical Officer.

Appointments.

A. BECKETT, M.R.C.S.E., has been elected Medical Officer and Public Vaccinator for the Blyth District of the Worksop Union, vice F. J. Wells, M.R.C.S.E., deceased.
 T. BOND, M.B., has been appointed Resident Medical Officer to the Public Dispensary, Carey-street, Lincoln's-inn, vice H. L. Kempthorne, M.D., appointed Resident Medical Officer to the Royal Hospital of Bethléhem.
 H. BRIEZYCKE, L.R.C.P.L., late of the Training Ship "Excellent," has been appointed House-Surgeon to the Sheffield Public Hospital, vice F. W. Cooper, L.R.C.S.Ed., resigned.
 T. W. BULLOCK, M.R.C.S.E., has been elected Medical Officer to the Warwick Union Workhouse, vice H. Blenkinsop, F.R.C.S.E., resigned.
 J. CARUTHERS, L.R.C.P.Ed., Medical Officer for the Portland District of the Weymouth Union, has also been appointed Registrar of Births, &c., Physician and Surgeon to the Royal Portland Dispensary, and Admiralty Surgeon and Agent for Portland, vice U. P. Brodribb, M.B., resigned.
 J. B. CLARK, L.F.D. & S. Glas., has been appointed Medical Officer and Public Vaccinator for the Parish of Balfron, via Glasgow, vice A. F. A. Fairweather, M.B., C.M., resigned.
 J. H. C. CONSTABLE, L.K.Q.C.P.I., L.R.C.S.I., has been elected District Medical Officer to visit Out-Patients of the Royal South London Dispensary, St. George's-road, Southwark, vice Dr. Swallow, resigned.
 Dr. Wm. DARLING, F.R.C.S.E., has been appointed Professor of General and Descriptive Anatomy in the University of New York.
 J. S. DENHAM, M.R.C.S.E., has been appointed Medical Officer to the Workhouse of the South Shields Union, Durham, vice James Williamson, L.R.C.P.Ed., resigned.
 A. F. A. FAIRWEATHER, M.B., M.C., has been elected Medical Officer and Public Vaccinator for the Parish of Garvald, Haddingtonshire, vice J. J. Hardesty, L.R.C.P.Ed., resigned.
 C. GAHOBY, M.R.C.S.E., has been elected Resident Medical Officer to the Worcester Dispensary, vice W. Woodward, M.D., resigned.
 W. HOYLE, M.R.C.S.E., has been appointed Medical Officer for the Atherton District of the Leigh Union, vice J. Croston, M.R.C.S.E., resigned.
 W. LANGSTON, M.R.C.S.E., has been appointed Medical Officer for the Pembroke District of the Kingston Union, Herefordshire.
 C. W. MACRURY, L.R.C.P.Ed., has been elected Medical Officer and Public Vaccinator for the Parish of Barna, Inverness-shire, vice Fraser, resigned.
 J. MOIR, L.R.C.P.Ed., has been elected Assistant House-Surgeon to the Ardwick and Ancoats Dispensary, Manchester.
 G. E. L. PEARSE, M.R.C.S.E., has been appointed Senior House-Surgeon to the Royal Infirmary and Dispensary, Manchester, vice G. Clements, M.R.C.S.E., resigned.
 F. S. RISK, L.K.Q.C.P.I., has been elected Resident Medical Officer to the Isle of Man Hospital and Dispensary, vice E. Snell, M.R.C.S.E., resigned.
 Mr. R. ROBINSON has been appointed Resident Dispenser to the Hitchin Infirmary, vice Coker, resigned.
 P. RUSSELL, M.B., has been elected Medical Officer for the Lurgan Dispensary District of the Lurgan Union, County Armagh, vice R. S. Hannay, M.D., resigned.
 Mr. G. STOCKWELL of Batley, has been appointed Certifying Factory Surgeon, vice G. Allbutt, M.R.C.S.E., deceased.
 J. WHITWORTH, M.D., has been elected Medical Officer for the Union Workhouse, Industrial Schools, and Infirmary of the Dewsbury Union, Yorkshire, vice G. Allbutt, M.R.C.S.E., deceased.
 E. P. YOUNG, M.R.C.S., L.S.A., L.M., has been elected Surgeon to the Westbourne Dispensary and Maternity, Paddington.

Original Communications, Hospital Reports, Society Proceedings, and other matter of considerable length, should reach our Office not later than FRIDAY EVENING for insertion in the following Wednesday's issue. No exception to this rule can be made. Important information—Telegraphic News, and other matter occupying only a short space—can be received up to Monday evening.

WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING JUNE 16TH, 1866

BIRTHS.

ACKLAND.—On May 24th, at Bideford, North Devon, the wife of W. H. Ackland, M.D., J.P., of a son.
 BIRD.—On May 2nd, at Seebpore, Howrah, the wife of Robert Bird, M.D., of a daughter.
 DEBENHAM.—On June 7th, at Heath House, Stepney, the wife of Robert Debenham, Esq., surgeon, of a son.
 DIVERS.—On June 6th, the wife of Edward Divers, M.D., of Queen's College, Birmingham, of a son.
 MEERES.—On June 4th, at Freshwater, Isle of Wight, the wife of Edward E. Meeres, M.D., of a daughter.
 NORTON.—On June 6th, at Westbourne Grove, Bayswater, the wife of Algernon C. W. Norton, M.D., of a daughter.
 ROOKE.—On June 11th, at Cheltenham, the wife of T. Morley Rooke, M.D., of a son.
 SMITH.—On June 2nd, at Burbage, Wilts, the wife of C. Swaby Smith, Esq., of a daughter.
 CURTIS.—On the 15th inst., at 8, Camden-place, Cork, the wife of James G. Curtis, M.D., of a daughter.

MARRIAGES.

BARTLETT—WATHEN.—William Penny, Esq., eldest son of William Bartlett, Esq., of Ladbrook Lodge, Notting-hill, to Mary Eliza, eldest daughter of the late J. R. Wathen, Esq., on June 6.
 COLGOURN—CARROW.—Sir Robert Colgourn, K.C.B., of Canstradden, to Ann, only daughter of William Cathrow, Esq., of 42, Weymouth-street, at St. Marylebone Church, on June 5.
 COXWELL—COOPER.—J. E. Grinfield, Esq., to Mary Gertrude, eldest daughter of George Lewis Cooper, Esq., of Woburn-place, at St. George's, Bloomsbury, on June 7.
 DON—ELLIOTT.—William Gerard Don, M.D., 28th Regiment, to Louisa Jane, second daughter of Captain Edward G. Elliott, R.N., at Plymouth, on May 7.
 EVANS—MELVILLE.—Henry K. Evans, Esq., son of Herbert N. Evans, M.D., of Tynawr, Brecknock, to Amelia Eleanor, only daughter of the late George H. Melville, Esq., of St. Helier's, Jersey, on May 31.
 FAULKNER—WEBSTER.—William Faulkner, Esq., of Rotherthorp, to Frances Anne, second daughter of F. T. Webster, Esq., Surgeon, St. Alban's, on June 7.
 FOWLER—COTGRAVE.—R. S. Fowler, Esq., of Bath, to Elizabeth Burgess, eldest daughter of Lieutenant-Col. Cotgrave, R.A., on June 12.
 GARDNER—GARRETT.—John Gardner, Esq., second son of John Gardner, M.D., of Montague-street, to Amy Vernon, second daughter of the Rev. Samuel Garrett, of Queen-square, at St. George's, Bloomsbury, on June 7.
 GARSIDE—SPENCER.—John Garside, Esq., Brownswoods, Congleton, to Sarah Emily, younger daughter of Lawrence Spencer, Esq., of Preston, on June 6.
 HALLOWES—LEACHMAN.—George B. Hallowes, Esq., third son of Price Blackwood Hallowes, Esq., Surgeon, of Canterbury, to Lucy Mary, youngest daughter of Joseph Leachman, Esq., Adelaide-road, Haverstock-hill, on June 5.
 KNOTT—MILWARD.—Middleton O'Malley Knott, M.D., of Castlebar, Ireland, to Sophia, eldest daughter of James Milward, Esq., Bidford, Warwickshire, on June 7.

DEATHS.

CHALDECOTT, William, Esq., Surgeon, at Holmwood, Dorking, aged 67, on June 1.
 LYSTER.—On June 3rd, at Liverpool, the wife of C. E. Lyster, M.D., of a daughter.
 MARTIN.—On May 26th, at Ipswich, Hannah, wife of Robert Martin, Esq., late of Holbrook.
 PARKINSON.—On June 2nd, at Kingstown, Ireland, aged 50, Sarah, widow of William H. Parkinson, M.D., of Brussels.
 RITCHIE, DAVID, M.D., late Deputy Inspector-General of Hospitals, Bombay Medical Service, at Dalgaire, Cupar Fife, on May 23.
 SHUTE.—On May 26th, at Greenwich, aged 23, Louisa, eldest daughter of Gay Shute, Esq., Surgeon.
 SURRAGE.—On June 3rd, at Downend, Henry J. L., only child of James Surrage, M.D., of Wincanton.
 STANLEY.—On June 6th, at 16, Westbourne-terrace, Catharine, widow of Edward Stanley, Esq., F.R.S.
 TUNALEY, Charles, M.D., at Millbrook-place, Harrington-square, aged 58, on June 5.

MATER MISERICORDIÆ HOSPITAL. CLINICAL LECTURES ON DISEASES OF THE HEART.

By Dr. HAYDEN,
PHYSICIAN TO THE HOSPITAL.

LECTURE I. MITRAL OBSTRUCTION.

Delivered Tuesday 19th.

GENTLEMEN,—I propose, in the course of the present session, bringing under your notice in a series of short clinical lectures, the subject of diseases of the heart, confining myself to those forms that have been illustrated by cases in our wards.

This hospital affords an ample field for the study of cardiac pathology, and, I trust, I may succeed in the endeavour to enlist your interest in the prosecution of it. The first subject I shall take up is that of contraction of the left auriculo-ventricular, or mitral orifice, because it is one upon which a considerable addition has been recently made to our knowledge, and in the diagnosis of which I do not hesitate to affirm, notwithstanding the scepticism of some of our most eminent authorities, that absolute precision has been arrived at, so far, at least, as that is attainable in medicine.

We have had under observation six cases of this form of disease of the heart since December, 1864. In five of these cases the diagnosis of mitral contraction was confidently made; in the sixth, the evidence upon which an opinion as to the state of the heart might be formed was suspended by the extreme debility of the patient, who was not seen by me till a few days before her death with cerebral complication.

In three out of the six cases we have had the advantage of a post-mortem examination, and the morbid specimens obtained are now before you.

I will give a short *resumé* of each of these cases, and subsequently make a few general remarks upon them, with the view of endeavouring to fix in your minds the most prominent symptoms and the diagnostic signs of this particular form of cardiac lesion.

Case 1.—A. K., an unmarried female, aged 28 years, a dressmaker, admitted into hospital December 7, 1864. Has suffered for the last few years from palpitation and shortness of breath on making much exertion; these symptoms have latterly become more troublesome. Twelve months previously she began to cough after exposure at night, and for four months preceding the date of her admittance into hospital she has not been able to lie down for more than a minute or two, owing to the dyspnoea which this change of posture occasioned. A month previously her feet began to swell, and about the same time, or somewhat earlier, and repeatedly since, she expectorated some fluid blood.

The feet and legs are now much swollen; the face is rather ruddy and not œdematous; pulse 96, weak, small, and irregular; heart acts with great irregularity, every third beat being followed by a rapid "tick tack," the time of recurrence of which, however, occasionally varies; impulse strong and laboured, but not heaving; first sound

somewhat rough but well pronounced; second sound double, reduplication being most distinctly audible to right side of apex; chest universally resonant and rather distended, a slight shade of dulness beneath right clavicle; respiratory sound rough, and accompanied with fine crepitant râles all over chest.

Venous pulsation, synchronous with the ventricular systole, of a tremulous character, and arrested by the lightest finger-pressure, is visible in both supra-clavicular fossæ, and also along inner edge of right sterno-mastoid muscle.

December 16th: Breathing much relieved by a large blister; râles less loud; a distinct, somewhat rough, but not loud murmur is heard over left apex *immediately before* and running up to first sound ("left auricular systolic murmur"); no reduplication of second sound to-day; pulse 96, and still irregular at intervals.

17th: Præsystolic murmur audible also, but not so distinctly, over lower part of sternum, not audible over left scapula, where sounds of heart are distinctly heard; pulse 102, occasionally intermitting, and so feeble that patient could scarcely be expected to have strength enough to stand, yet she walks about the ward and corridors, and declares she feels "better;" no lividity of lips or fingers; a good deal of blood-streaked mucus expectorated last night.

31st: Shooting pain in region of heart extending to left scapula; fremitus over apex; palpitation and breathlessness; pulse 112, small and intermitting; one leech to be applied over heart, and one-eighth of a grain of extract of aconite to be given three times daily.

January 11th: A murmur audible *with* first sound as well as preceding it.

12th: The former, or systolic murmur, *only* audible to-day.

13th: *Both* murmurs again audible. R. Extract. acon. gr. $\frac{1}{2}$; pil. scillæ c. gr. v. M. Ft. pil. One such to be taken three times daily.

14th: Great distension of cervical veins, with respiratory pulsation on right side; cardiac pain shooting to left scapula; great œdema of legs and feet. R. Ext. elaterii, gr. $\frac{1}{2}$; pil. scillæ c. gr. iiss.; ext. hyoscyami, gr. i. M. Ft. pil. habeat ii. tales, st. i. 6ta quaque hora.

21st: Neither radial pulse perceptible; considerable œdema of right arm on which she lies; great œdema of legs, which were punctured, and gave off much serum with some relief. R. Ext. aconit. alcohol. gr. $\frac{1}{2}$, to be given three times daily in form of pill.

22nd: No pulse to be felt; pain over heart and also in right side posteriorly; base of right lung somewhat dull, with crepitus; systolic murmur *only* audible; second sound reduplicated at midsternum.

23rd: Patient is sinking; no pulse; respirations 18 in the minute; great venous pulsation in neck; hands icy cold.

24th: Respirations 15 per minute; is unconscious; face livid.

25th: Coughed up some dark clotted blood last night; still unconscious; respirations 15.

26th: Died at two o'clock this morning.

Autopsy nine hours after death.—Face, trunk, and extremities livid and œdematous. Both lungs emphysematous; lobular apoplexy of both apices, more extensive in right, and also in both bases; in left base a group of emphysematous air-sacs, the size of a large walnut, projects from the surface of the lung, and is filled with dark solidified blood; surface of lungs is slate-coloured in site of apoplectic effusion. About six ounces of serum were found in the pericardium. The heart was greatly dilated owing to distension of its right cavities, which contained a vast quantity of dark currant jelly-like blood; right auricle and ventricle much dilated, and tricuspid orifice so large that the five fingers might be passed through it with ease; the anterior and left segment of the tricuspid valve presented upon its edge several warty growths of minute size but firm consistence; a few vegetations of a

similar kind were likewise found on its posterior segment. The walls of the right ventricle were somewhat thickened (being five-sixteenths of an inch); the left auricle was much dilated and its walls thickened; the pulmonary veins were not dilated. The mitral orifice consisted of a funnel-shaped passage formed by the agglutination of the segments of the mitral valve, and projecting into the left ventricle. This passage is an inch and a quarter long, and so narrow at the end as barely to admit the point of the little finger. The segments of the valve, as likewise the chordæ tendinæ, are much thickened. A fragment of solid fibrin, of a quadrilateral figure, was attached by one of its edges to the auricular aspect of the mitral valve in such a manner that it must have been displaced over the orifice during the passage of the blood from the auricle into the ventricle.

The left ventricle was contracted and of normal thickness.

The sigmoid valves, both of the aorta and pulmonary artery, are in a healthy state; there is slight atheromatous degeneration of the coats of the aorta above the valves.

In this case the diagnosis of mitral contraction was made and confidently announced on the 16th of December, the day on which the præstolic apex-murmur was first distinctly recognized.

Dilatation of the right chambers of the heart and tricuspid regurgitation were declared present on the day of the patient's admittance into hospital. Pulmonary apoplexy was identified a short time before the patient's death.

I have given you the details of this case, because it is a typical example of the particular form of disease of the heart which it exemplifies, with the clinical history of which you should be acquainted. It was submitted to the Pathological Society of Dublin, together with the morbid specimens which are now before you, on the 28th of January, 1865, and will be found fully reported in the *Dublin Quarterly Journal* for November of that year.

Case 2.—Ellen D., aged 30, mother of five children, admitted into hospital January 10, 1865. A fortnight after her last confinement, which took place a fortnight ago, had a "fit," during which she was unconscious, and on recovery found she had lost entirely the use of the right arm, and partially also that of the lower limb of the same side; sensibility is only impaired in both limbs; the mouth is slightly drawn towards the left side; pulse 102, weak, and remarkably irregular, as is likewise the heart's action, which is, however, unattended with murmur.

14th: Second sound of heart doubled.

February 1st: A loud rough murmur immediately precedes the first sound, which is unaffected; second sound double. Patient remembers now that seven or eight years ago she suffered from palpitation after exertion; has never had rheumatism or spat blood; no œdema in any part of body.

10th: Pulse 84, irregular and failing. Left hospital on 26th February much improved in general condition, but without any improvement as regards the paralysis. The treatment in this case consisted in the administration of bichloride of mercury and iodide of potassium, with the view of promoting resorption of the extravasated blood or cerebral embolus to which the paralysis was attributed; subsequently strychnine was given in one-sixteenth grain doses three times daily.

Case 3.—Jane L., aged 30, mother of four children, living at Stillorgan, visited the hospital dispensary June 14, 1865, complaining of languor and debility. She is pale; pulse 96 and "visible;" respiration natural; heart's action strong; loud rough murmur preceding first sound, and confined to region of apex; this murmur occupies latter part of diastolic pause, and ends at first sound, which is heard distinctly, unaccompanied by murmur. Second sound is double over apex where it is loudest, also over base and ascending aorta. One of the junior students present who examined the heart remarked that it seemed to him as if there were "three sounds."

Patient had acute rheumatism, engaging knees and elbows, four years ago, but has no reason to suppose that the heart was then implicated. Seven months ago spat about a pint of florid blood, and a little, which was of a darker hue, three weeks since. Slight rale in left mammary region; no œdema or dyspnoea.

June 21st: Patient visited the dispensary again to-day! is much better; pulse 90, full and regular; when heart acts strongly, as after exertion, a jarring fremitus is felt over apex; other phenomena as before.

The treatment consisted in the administration of iron and quassia.

Case 4.—Jane G., aged 34, married, but without children, was admitted into hospital January 26, 1866. Had rheumatic fever when thirteen years old, but has no recollection of heart having been engaged in that attack, and enjoyed good health subsequently; had occasionally had hæmorrhage from the bowels, which she attributes to "piles." Three years ago received from her husband, whilst under the influence of drink, a blow in the region of the liver, by which she was stunned; suffered pain in this situation, and shortly afterwards became dropsical; has not been jaundiced. The feet and legs were greatly swollen, as was likewise the abdomen. The former were punctured, and after a short course of medical treatment she got quite well of the dropsy, and enjoyed comparatively good health till six weeks ago, when she caught cold from wet and exposure during the voyage from Liverpool to Dublin. Shortly afterwards the feet and legs became swollen, and the breathing oppressed.

On admission, the lower extremities were livid and patchy, and enormously distended with serous infiltration. The toes were purple in colour; some apertures had formed spontaneously in the legs, and from these serum exuded. Pulse small and weak, but regular; orthopnoea; lips livid; conjunctivæ injected, and of a purple tint, with an admixture of jaundice; hands and fingers cold and livid; respiration greatly oppressed; jactitation; urine passed in small quantity (not more than three ounces in twenty-four hours, and loaded with bile-pigment).

Owing to the distress which change of posture occasioned, it was impossible to examine the chest posteriorly. It was, however, dull below and in front, and to an extent sufficient to obscure præcordial dulness. Cardiac impulse of ordinary strength and accompanied with slight fremitement. The apex pulsated in the usual situation, and here two distinct murmurs were heard; the first in the conventional order of cardiac phenomena was loud and rough, and preceded the first sound by an appreciable interval; it was limited to the area of the apex and succeeded by the first sound, which was clear and unattended with murmur; the second murmur was less distinct here, softer and more distant; it was diastolic in rhythm, and superseded or replaced the second sound; was loudest at the base, where it was the only murmur distinctly heard, and was traceable upwards in the course of the aorta for about two inches.

Slight disfigurement of hands and fingers from chronic gout, and some serous effusion into peritoneum.

Diagnosis.—Mitral obstruction; partial aortic regurgitation; disease of liver, probably cirrhosis, with effusion into all the serous cavities.

Prognosis in the highest degree unfavourable; death imminent within the next few days.

January 27th: Passed a sleepless night; punctures discharged very little; two patches of gangrene the size of a crown piece, one upon the dorsum of each foot; no radial pulse; great dyspnoea and agonizing pain in the abdomen.

28th: Patient died at half-past one o'clock this morning, having previously thrown up a large quantity of dark coagulated blood.

Autopsy ten hours after death by the Resident-Surgeon, C. O'Neill.—Much serous effusion into peritoneum; liver contracted and firm, with thickened capsules; much reduced in volume, somewhat globular in figure, and on

section was found to be in the condition described by Kiernan as that of "portal venous congestion." Spleen of average size, firm and heavy; capsules thick and opaque on convex surface. In the substance of the spleen were imbedded several masses of a mortar-like substance, as large as a bean, perfectly encysted, and consisting apparently of lithate of soda. Kidneys healthy; no evidence of peritonitis. Thorax: a large collection of serum in each pleural cavity; lungs healthy, with exception of bases, which were solid and dull on percussion and opaque on surface, owing to thickening of fibrous investment. On section this portion of each lung was firm, dark red, and did not yield either blood or serum. Pericardium contained about a pint of straw-coloured serum. The surface of the heart was as if universally daubed over with white paint, but polished and glistening; its fibrous envelope was greatly thickened. A flake of white membrane was found floating loosely in the liquid effusion. Heart of average size and consistence. Right auricle contained a large mass of yellow fibrine, ending in a rounded extremity at the auriculo-ventricular opening. Right ventricle of average thickness, somewhat dilated, and containing a few shreds of decolorised fibrine. Pulmonary artery free and healthy. Left auricle somewhat thickened in its walls (see measurements). Left ventricle contracted and thickened. Mitral valve rigid, much thickened, and nearly calcified. The segments were united in such a manner as to convert the auriculo-ventricular opening into a narrow slit-like passage opposing the free entrance of blood into the ventricle, but scarcely admitting of regurgitation. The aortic valves were somewhat thick and rigid, but not in an advanced stage of disease; they permitted the slow entrance of water from the aorta into the ventricle. The lining membrane of the aorta was red and dotted with yellow patches of atheroma.

Measurements of Heart.—Walls of right ventricle $3\text{--}16$ ths of an inch thick at apex, and $\frac{3}{8}$ th of an inch in central portion. Right auriculo-ventricular valve consisted of only two segments, the septum of Lieutaud being absent.

Left Auricle.—Cavity $2\frac{1}{4}$ inches from septum to outer wall, $2\frac{3}{4}$ inches from superior wall (near appendix) to root of mitral valve, 3 inches from anterior to posterior wall; thickness of walls in sinus, $\frac{1}{4}$ inch.

Left Ventricle.—Cavity, from root of mitral valve to apex, $2\frac{1}{2}$ inches; antero-posterior diameter near attachments of septum, $1\frac{1}{4}$ inch; thickness of walls, $5\text{--}16$ ths of an inch at apex, $\frac{1}{2}$ inch at central portion, $\frac{3}{8}$ inch at base; aorta 1 inch in diameter immediately above valves.

This case admitted of no hope from treatment, which was, therefore, confined to palliative measures, such as brandy and etherial stimulants, warm applications to the feet, occasionally small doses of blue pill and extract of taraxacum, with the view of quickening the action of the liver, and liquid nutriment.

The details of the case, together with the morbid specimens, were laid before the Pathological Society of Dublin on the 3rd of February last.

The next case was complicated with right hemiplegia, atrophy of the left anterior lobe of the cerebrum, and loss of speech, and has been fully reported in THE MEDICAL PRESS AND CIRCULAR of May 23, as a good example of aphasia. I will here give only an epitome of the case, dwelling upon those portions of it which have reference to the cardiac lesion.

Case 5.—Jane Q., aged 47, married, and the mother of one child, admitted into hospital March 17, 1866. Health has been good, with exception of a few attacks of rheumatism. On the night of the 27th of last December went to bed in her usual health, and on the following morning was found hemiplegic on the right side, and incapable of uttering a word beyond the monosyllables, "yes" and "no;" there was also paralysis of the right side of the face. At the date of admittance her condition had undergone no change as regards voluntary motion in the right side and the faculty of speech; pulse so weak that it was not cal-

culable at the wrist; counted by the heart it was 160; heart's action most irregular, both sounds morbidly clear, extensively transmitted over the chest, and *unattended with murmur*.

Under date of 23rd March, it is reported in my notes that there had been no radial pulse for the two preceding days, and on the following day (March 24th), the action and sounds of the heart had ceased to be perceptible; patient conscious and can swallow liquids; coldness and lividity of extremities, the latter in patches; died at four p.m.

Autopsy twenty-four hours after death.—It is unnecessary to describe here the condition of the brain, which was of deep interest, and confirmatory of the views of M. Paul Broca as regards the connexion between atrophy of the second and third left frontal convolutions of the cerebrum and loss of speech. The details are given in THE MEDICAL PRESS AND CIRCULAR of May 23rd, and will be published, together with an admirable woodcut of the brain, in the proceedings of the Pathological Society, to which the case was communicated on the 7th April last. The heart was of average size, the left auricle dilated and its walls hypertrophied (see measurements below), and the left auriculo-ventricular orifice much contracted by cohesion of the segments of the mitral valve.

Left auricle one-fourth of an inch thick at superior and left portion; do., one-eighth of an inch thick in central portion; left ventricle, one half inch thick in central portion; do., one-fourth of an inch thick at apex.

The mitral orifice barely admitted the tip of the index finger. The left lung presented a good example of pulmonary apoplexy. The morbid specimens illustrative of the heart and lung complication are now before you, and I will proceed to make a few remarks on this portion of the case.

I entertain no doubt whatever that this poor woman was the subject of endocarditis, implicating the mitral valve, and causing partial cohesion of its segments in one of her attacks of rheumatism; this was the starting point of her disease and the immediate cause of her death. On the night of the 27th of December, the woman being then in her usual state of health, a fibrinous embolon was, in all probability, detached from the mitral valve, wafted along by the arterial current, and impacted in the left middle cerebral artery, whence the left anterior lobe of the cerebrum and the upper portion of the left motor tract derive their principal nutrient supply; hence paralysis of motion on the opposite side and loss of articulate speech.

It is true that an embolon has not been found, and therefore there is not proof that this was the cause of the symptoms mentioned; still, the sudden occurrence of a local cerebral lesion, not apoplectic, the patient being in her usual state of health up to the time of its occurrence, taken in conjunction with pre-existing valvular disease due to inflammatory deposit on the arterial side of the heart, will admit of no other solution, and affords circumstantial evidence so strong that even in the absence of the peccant body at the period of death, and of a satisfactory explanation of its disappearance, I am forced to assume its existence on the night of the 27th of December, and for some time subsequent to that date; it may have been disintegrated and have re-entered the circulation in a molecular form; but on this part of the subject I will not further speculate.

The diagnosis of mitral contraction was not made in this case, because the pathognomonic sign of præ systolic apex murmur was not present. This sign, which I believe to be inseparable from mitral constriction, as long as the left auricle contracts with ordinary force, ceases to be developed, as indeed all cardiac murmurs do, some time previous to death, owing to debility of the heart.

In this particular form of cardiac disease it is remarkable, and in my opinion likewise characteristic, how long the patient may exist without a radial pulse. Thus, in Case 1, I find the following remark in my notes on this subject, under date December 17, *forty days* before the patient's

death: "Pulse 102, and so weak the wonder is she is able to stand; yet she walks about the wards and corridors quite firmly, and declares she is better." On the 21st of January neither radial pulse was perceptible, nor was it to be felt at any time subsequent to this date, although the patient lived till the 26th—that is, for a period of *one hundred and twenty hours*, with absolutely no pulse at the wrist.

In the case now under consideration (Case 5) the radial pulse was so weak on the 17th of March (the day of admittance) that it could not be registered; on the 21st, and after that date, there was no radial pulse, yet the patient lived till four p.m. on the 24th—*i.e.*, *seventy-two hours* after pulsation at the wrist had ceased.

The preceding considerations may afford an explanation of the absence of præ systolic murmur in a case of veritable mitral contraction, seen only during the more or less protracted period of profound debility immediately preceding death.

The other signs and symptoms characteristic of mitral contraction were present in the case under notice, but obscured by the more prominent symptoms arising from the cerebral lesion; thus, the pulse was flickering and intermittent, and ultimately failed altogether some time before death; there was comparatively little venous engorgement or lividity of the surface or extremities, such as are witnessed in patients suffering from mitral regurgitation, for the obvious reason that the circulation by the arteries being in defect, the systemic veins were consequently not surcharged with blood, as they are in the last-mentioned form of disease. This difference is probably due to the fact, that in mitral regurgitation the left ventricle is in a state of hypertrophy, and therefore acts with compensatory force upon the column of arterial blood escaping by the aorta, whilst at the same time it exercises an unwonted back pressure upon the pulmonary circulation through the patent mitral orifice, and thus upon the venous side of the heart, whereas in mitral contraction left ventricular hypertrophy does not exist, and mitral patency, if at all, only in a very moderate degree. Consequently the pressure upon both ends of the circulating column is much less, and the volume of blood escaping by the aorta being already much reduced, the pulse is small and faltering, and reflux upon the lungs, and through them upon the right side of the heart, is less in quantity and in force.

For the reasons just given respiration is much less embarrassed, and dropsical effusion less general and less considerable in mitral obstruction than in mitral regurgitation; but whatever the cause may be the fact is as now stated.

The action of the heart in cases of mitral contraction is likewise peculiar; it is quick, weak, markedly irregular, and of the "tick-tack" character; and the sounds are sharp and propagated to a great distance over the chest. The second sound is also not unfrequently *reduplicated*; this occurred in at least two of the cases in the present category. It is not easy to explain this phenomenon; the most rational view consistently with our present knowledge is that which attributes it to a want of synchronism in the closure of the aortic and pulmonic valves. In mitral contraction the great difference in tension of the aorta and pulmonary artery may cause a corresponding difference in the period of closure of the two sets of valves.

The last case I shall submit to you has been recently under your observation, and therefore you will remember all the particulars connected with it.

BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—Dr. Browne, R.N., the treasurer of this branch of the above society, thankfully acknowledges to have received the sum of £5 as a subscription from the Marquis of Londonderry, per James Brownlow, Esq., J.P.; and of £2 4s. from Dr. A. A. Stewart, Staff-Assistant-Surgeon, Fort Victoria, West Coast of Africa, per Dr. R. Stewart, hon. secretary.

## CASE OF HÆMORRHAGE FROM THE RECTUM.

By GEORGE W. BALFOUR, M.D., F.R.C.P.E.

ON the 17th of March last I was requested to see a young man, aged 21, formerly robust and healthy, never having had a day's illness, but now feeble, anæmic, and confined to bed from pure debility. He stated that he had just returned from London, having been unable to keep his situation there from continually increasing weakness, that for six months past he had lost blood daily at stool, and this drain was, so far as he knew, the sole cause of his debility. I ascertained that he had only one stool every day, in the morning, but that after it a quantity of bright red blood, amounting usually to about two ounces, escaped and coagulated in the pan; the stool was rather small for a man of his build. He had no piles, either external or internal, and there was apparently nothing to account for this debilitating hæmorrhage. I requested my friend Mr. Annandale to see him with me on the 23rd; he made a most careful examination of the rectum, but could discover nothing wrong, either internally or externally, except a slight natural—by no means spasmodic—stricture of the sphincter. Recalling to my mind the interesting observations made by Mr. Syme on hæmorrhage from the rectum in his "Clinical Observations on Surgery," Edin., 1861, and in particular the remarks he has made at p. 85 upon this apparently natural peculiarity as one cause of such hæmorrhage, Mr. Annandale proposed to divide with a bistoury the mucous membrane of the bowel, with a few of the internal fibres of the sphincter; this was accordingly done at once, and a piece of lint put between the lips of the wound. My patient's bowels were moved the next day without medicine, and—with the exception of a streak or two from the wound—without hæmorrhage for the first time for six months. In the course of a few days the little wound was entirely healed, and a satisfactory stool continued to be passed without any blood till the 13th April, when a teacupful of blood was passed immediately after his stool. On the 14th a similar quantity of blood was passed in a similar manner, and I asked Mr. Annandale to see him with me next day. On the 15th a mere trace of blood was passed along with the stool, and on a careful examination by Mr. Annandale the incision was found perfectly healed, and everything else normal. Mr. Annandale then informed me that Mr. Syme had occasionally observed a slight recurrence of the hæmorrhage at irregular intervals after the performance of this operation in similar cases, these hæmorrhages, however, having no detrimental influence on the ultimate success of the operation, and he suggested that such might be the case in regard to this patient. I am glad to say that this has been the actual result, and that my patient has, up to this date (June 12), had no recurrence of hæmorrhage, that his health is now completely restored, and that he is now prepared to return to business, with his strength perfectly renovated.

No explanation has been ever attempted to be given of this remarkable peculiarity, this curious dependence of hæmorrhage upon a conformation so slightly abnormal. It is difficult, indeed, to see how this remarkable phenomenon could be explained, and it is indeed fortunate for our patients that no explanation is required. The practical sagacity of Mr. Syme has empirically solved the difficulty, and placed in our hands a remedy at once simple, easily applicable, and successful, and I have much pleasure in recording, for the benefit of other sufferers, so remarkable and successful an instance of such a simple cure for an affection so debilitating, and so certain, if unrelieved, of proving ultimately fatal.

18, Lynedoch-place, Edinburgh.

ALUMINIUM.—A trial has just been made at Florence of a cuirass in aluminium, which is as light as an ordinary waistcoat, nearly as flexible, and capable of turning a musket ball fired at the distance of thirty-eight paces and of resisting a bayonet thrust from the heaviest hand.

Hospital Reports.

MERCER'S HOSPITAL.

CASES OF LOSS OF SPEECH (APHASIA) WITH HEMIPLEGIA.

(Under the care of Dr. MCORE.)

OCCASIONAL TOTAL SPEECHLESSNESS—IMPERFECTION OF SPEECH AT ALL TIMES—RIGHT HEMIPLEGIA.

[Reported by Mr. ALBERT F. L'ESTRANGE.]

Case 1.—Frederick H—, aged 29, a shoemaker by trade, was admitted into Mercer's Hospital on the 14th March; his face was pale and puffy looking; his right pupil more dilated than the left; his voice was thick and he spoke slowly and drowsily, and as if he had not control over his tongue, and he was occasionally at a loss for a word. He had manifest loss of power over the right leg and the right arm, and betrayed great emotion on being asked as to the duration of his illness, &c.

He stated that about two months before his admission, whilst at work, he was suddenly seized with severe headache; this passed off, but ere long was followed by pain down his right side and leg; he attempted to rise from his seat and in doing so fell. On being assisted, his legs refused to support him, and he had total loss of power over the right arm. He could not see with the right eye; and on being spoken to by his wife he was unable to articulate a single word, although perfectly conscious that he was spoken to. In this speechless condition he remained for two hours. After the lapse of some days he regained comparatively the use of the right arm and leg, and his power of speech. About a week after this attack he again felt a quivering sensation in his lips and sense of uneasiness generally, which he attempted to battle over, as he said, by going into the air. This restored him somewhat, and he went into an adjoining shop to buy a weekly newspaper, but on arriving at the counter was unable to ask for it or articulate a single word, although he was perfectly conscious all the time what he wanted. In about fifteen minutes he again recovered his speech. His muscles generally were flaccid, and his heart's action very feeble; he suffered from constipation. His urine was slightly alkaline, but contained no albumen; its specific gravity was 1016. His father and mother are both alive and in good health, and all his brothers and sisters are healthy. During his stay in hospital he had no return of the total aphasia; but his speech was drowsy and interrupted, whilst no improvement was perceptible in the hemiplegia.

IMPERFECTION OF SPEECH—MISPLACING WORDS—LOSS OF MEMORY—RIGHT HEMIPLEGIA WITH DEVIATION OF THE EYES.

Case 2.—Joseph —, aged 55, a carpenter by trade, was admitted into Mercer's Hospital on the 5th March last suffering from paralysis of the right half of the body. He appeared flushed, and the temporal arteries in both sides were very visible, more especially the right; his mouth was drawn to the left side whilst the tongue, when protruded, pointed towards the right side. He had lateral deviation of the eyes to the left side, but no abnormal condition of the pupils; the paralysis of motion of the right side was complete, and his speech was quite unintelligible. After some days he was able to give the following history of himself:—About a year and a half ago, whilst engaged in building a house in Drogheda, he suddenly felt heavy, fatigued, and unable to continue his work; next day he was worse, his vision having become indistinct and his speech affected. On the third day, not feeling better, he set out for Dublin, and whilst in the train was seized with violent headache and vomiting, and with difficulty could distinguish the passengers in the carriage with him. He

underwent some active treatment at this time, but although he improved, and was able to resume his work after some time, still his powers of calculation and memory generally were seriously impaired; for instance, he would frequently take up a tool and forget what use to make of it, and he would occasionally transpose or misplace words and names. On the 2nd of March last he was seized with loss of power of the right side, accompanied by loss of speech as already described. He confesses to have been a hard drinker, having had syphilis and a heavy fall on his head some years ago. His head was shaved, and a blister applied over the vertex. He got one-sixteenth of a grain of biniodide of mercury in syrup of bark three times a day, and the vesication was kept up. In a few days his speech was comparatively restored, but still he spoke drowsily, and at the end of a fortnight he left the hospital, the paralysis of motion of the right side being barely perceptible.

EPILEPTIFORM CONVULSION—RIGHT HEMIPLEGIA—APHASIA.

Case 3.—James D—, aged 40, was admitted into Mercer's Hospital in November last. He was completely hemiplegic on the right side, and there was partial anæsthesia. At this time he was speechless, but when spoken to he seemed to understand what was said to him, being at the same time unable to repeat a single word, even when called into his ear. After a few days his efforts to speak might be best described as "an incoherent jumble;" still later he could say some words intelligibly, others he would attempt, and give them up in despair, then he would misplace them, and be perfectly conscious of having done so. Finally he left the hospital, speaking slowly and drowsily, but yet he could be understood. The treatment employed in this case (and which was repeated) consisted of blisters over the vertex, with the internal exhibition of iodide of potassium.

HEMIPLEGIA OF LEFT SIDE—NO IMPERFECTION OF SPEECH.

Case 4.—Jane McG—, aged 62, was admitted into Mercer's Hospital in March, 1866. On admission she had complete loss of power of the left side, but her speech was intact.

Dr. Moore, in commenting on the above cases, observed that the subject of aphasia (or loss of speech) accompanying right hemiplegia (disease of the left half of the brain) was engaging a great share of attention whilst it was found that left hemiplegia (disease of the right half of the brain) does not entail such a phenomenon, and such a result the above cases go to prove.

He dwelt on the pathological researches of Sanders and others, which fix the seat of this lesion in the external left frontal convolution of the brain, where the anterior lobe meets the middle lobe, immediately on front of the fissure of Sylvius; and he concluded his remarks by stating that his late distinguished colleague and accomplished physician, Dr. Jonathan Osborne, had contributed a most valuable memoir on this subject to medical science nearly half a century ago.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

CASES UNDER THE CARE OF MR. PORTER,

SENIOR SURGEON TO THE HOSPITAL.

[Reported by ARTHUR WYNNE FOOT, M.D.]

(Continued from page 655.)

FRACTURE OF THE INFERIOR MAXILLA.

Case 21.—During the present month a cab-driver, 20 years of age, applied at the hospital for advice about an injury of his lower jaw, received on the previous night, by a fall from his cab while in a state of intoxication. Examination, a fracture was discovered about a quarter of an inch to the left of the symphysis menti. He was in

pain; the pain was aggravated by attempts at mastication. There was slight irregularity in the line of the teeth at the injured side of lower jaw, with some mobility of the parts, and crepitus; increase in the flow of saliva was not noticed. The adjacent teeth on either side of the line of the fracture were fastened together by a metallic ligature; a gutta-percha splint, neatly moulded to the part, and padded with lint, was applied to the lower border of the chin and along the body of the jaw, and kept in position by means of a double-headed roller, with a split in it for the chin.

Mr. Porter remarked upon the great degree of direct violence generally necessary to cause fracture of this bone, the strongest of the bones of the face; upon the situation of the fracture in this case, which was that where the bone is most usually broken in adults—between the symphysis and the insertion of the masseter muscle; upon the propriety of speaking of fractures of the lower jaw as compound, laceration of the gums or mucous membrane of the mouth almost always allowing of the access of air in some degree to the fissure; and upon the advantage of securing steady apposition of the adjacent teeth by metallic in preference to silken ligatures—a practice known to and approved of by Hippocrates.

HYDRARTHROSIS AFFECTING THE KNEE-JOINT—TREATMENT BY PRESSURE.

Case 22.—A delicate-looking girl, 18 years of age, was admitted into hospital the first week in June with a chronic effusion in the right knee-joint. The cause of the accumulation of fluid was obscure, there being no history of injury, acute inflammation, or of rheumatic or strumous affection of the joint. The knee was observed to "swell" three years ago, and had been of its present size for at least a year. Fluctuation was very distinctly obtained, the patella was floated out forwards, away from the femoral condyles, extension of the leg was performed with difficulty, unless with the assistance of the left foot, from the partial displacement forwards of the great extensor tendon and its sesamoid bone by the effusion into the joint and into the sub-crural sac above the knee-joint. There was no change in the skin, nor was pain present to any great degree. Comparative measurements made on the 7th of June were as follows:—

	Sound.	Morbid.
Above patella ...	13 $\frac{3}{4}$...	16 $\frac{1}{4}$ inches.
Across " ...	13 $\frac{7}{8}$...	17 $\frac{1}{2}$ "
Below " ...	13 ...	13 $\frac{1}{4}$ "

Upon the same day, the parts having been sponged with camphorated spirits, the emplastrum ammoniaci cum hydrargyro, spread on holland, was tightly applied in strips over the swelling, and the parts of the limb immediately above and below it; and she was prescribed iodide of potassium, with liberal diet and strict rest. Ten days afterwards, when the strapping, now become loose, was removed, the comparative measurements were:—

	Sound.	Morbid.
Above patella ...	13 $\frac{3}{4}$...	15 $\frac{1}{4}$ inches.
Across " ...	13 $\frac{7}{8}$...	16 $\frac{1}{4}$ "
Below " ...	13 ...	13 "

Fresh plaster was applied immediately as before.

Mr. Porter drew attention to the position of the patella as a diagnostic mark between synovial and bursal effusions, to the many evidences of the passive chronic nature of the effusion, indicating some latent constitutional cause for the morbid condition, and alluded to the various methods of treatment remaining in reserve should pressure prove too tedious or ineffectual, such as vesication, puncture, and injection of the synovial membrane of the joint.

TUMOUR INVOLVING THE OPTIC NERVE—PROTRUSION OF THE GLOBE—AMAUROSIS—EXTIRPATION OF THE EYEBALL.

Case 23.—A young woman, 24 years of age, was admitted with her right eyeball protruding from the orbital cavity, so much so that the upper eyelid frequently slipped

behind the summit of the globe, becoming locked there, and giving rise to a very uncomfortable sensation of the eye "being out on her cheek," until she pushed the ball backwards with her finger, when the lid could be returned to its place. The tarsi could not be brought into contact. The ball was directed downwards and outwards, the pupil fixed midway between dilatation and contraction. She was, moreover, blind, and had been so for four years. The eyeball commenced to come forwards about the time she lost her sight. She did not become suddenly amaurotic, but described her sight as "stealing away." She had latterly been subject to hemiparesis on the same side, feeling as if she received a sudden blow from a stick on the right side of the head, and sometimes as if "something started in that side of her head." There were no subjective phenomena of colour or vision in the eye; the globe was not itself enlarged, nor its motions impaired. The conjunctiva was not very much injected. The lids were uninfamed. The other eye was healthy and natural in all respects. There was no affection of the heart or thyroid body.

With the view of replacing this useless organ by a glass eye, and of relieving her from a source of constant distress, disfigurement, and alarm, Mr. Porter removed the globe, having first made an exploration of the post-ocular region.

On removal, the globe of the eye was not found to be enlarged, nor the orbital fat in excess, but an irregular shaped, soft pinkish mass closely surrounded the optic nerve as it penetrated the fundus of the globe, the tumour being at this place so identified with the nerve as to be inseparable from it. The growth was not a vascular one, nor did it present the physical appearances of encephaloid disease, while its colour and situation excluded the probability of its being any other form of cancer. Microscopic examination of the tumour resulted in some contrariety of opinion as to its malignant or non-malignant nature, but as the specimen is still under examination its structure will no doubt be ascertained.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

MISCELLANEOUS NOTES.

Scarlatina and Rheumatic Arthritis.—Mary Jane Coleman, aged 14, was admitted into the Hardwicke Hospital on the 25th May, 1866, under Dr. Lyons's care. On admission she had violent pain in the head and back, and but slight sore throat, and a dusky hue of skin, partly due to defective ablation. On the following day well-marked scarlatinal eruption made its appearance on the chest, arms, and legs. She was placed on three-grain doses of the chlorate of quinia, with perchloric acid. Under this treatment she steadily convalesced. When about two days up she was attacked with pains in several joints, and soon exhibited well-marked phenomena of rheumatic arthritis, which affected both knees, the ankles, and some of the minor joints. She was placed at once on the triple combination of potash salts (carbonate, acetate, and nitrate of potash in infusion of gentian) usually employed in Dr. Lyons's Clinique. The joints were carefully poulticed with chamomile flowers and poppy heads, and small doses of opium were given at intervals, to allay pain and procure sleep. This case progressed most favourably, the patient being fully convalescent in eight days, and she was shortly after discharged, the heart remaining perfectly intact.

The association of the rheumatic condition with that of scarlatina, which is occasionally witnessed in these countries, is more familiar to observers in the East and West Indies, some of the southern states of North America, and the ports which border the Gulf of Mexico. It has been witnessed in New York, and in the eastern hemisphere at Calcutta, Rangoon, and other British stations. Under the

name Dengue, or Scarlatina Rheumatica, it has on many occasions and in many of the localities above cited exhibited a very manifest epidemic tendency, and has usually been regarded as infectious. Painful swellings of the smaller joints, and occasionally of the testes, and the lymphatic glands in the neck, axilla, and groin, are observed to arise in connexion with the red rash and sore throat of scarlatina. In this form of affection the rheumatic diathesis and the scarlatinal malady co-exist and proceed *pari passu*. In this point of view the rheumatic affection stands in a somewhat different relation to the specific pyrexia in the class of cases to which that just cited from Dr. Lyons's Clinique, as well as those usually observed in these countries and on the continent of Europe, ordinarily belong. In this latter form, the rheumatic affection usually occurs as a sequela of the scarlatina, but the pathological relation of the two maladies is perhaps not for this reason the less clear. The not infrequent occurrence of cardiac complication in scarlatina (ordinarily in the form of pericarditis), with or without distinct arthritic affections, is worthy of note in considering the pathology of the disease and its affinities with other morbid states.

Scarlatina with mixed eruption.—A boy, aged 12, was admitted into the Hardwicke Hospital with mild sore throat and an eruption of an obscure and somewhat complicated character. A general dusky-red tint pervaded the entire skin, and mixed therewith was observable to the sight and touch a vast number of thickly-set, very minute pustules, granular in the feel which they presented to the hand when passed over the surface, and, when viewed closely, exhibiting minute yellowish-white points of partially concreted purulent matter. It was a point of some difficulty, as well as interest, to decide at once what the nature of the affection was. Having regard to the presence of sore throat, though in very mitigated form, and the claret colour of the fauces and tonsils, and bearing in mind other complicated and anomalous form of the disease which he had previously seen, Dr. Lyons came to the conclusion, that the case was one of scarlatina in which the proper eruption of that disease was to some extent masked by the occurrence of a minute pustular eruption. This diagnosis was confirmed by the more full development of the scarlatinal rash on the following days, when it went through its ordinary course to desquamation, outstripping the slower progress of the minute pustular eruption, which took many days to mature and fade. In ordinary cases the diagnosis of the eruptive fevers is not attended with difficulty, but few practitioners of experience can have failed to meet cases in which an absolute diagnosis seems at times impossible. Dr. Lyons, in commenting on this case, alluded to one in which for days successively there was an alternation between the phenomena of measles, scarlatina, and the very earliest stage of the small-pox eruption, and the case wound up favourably without its being possible to assert in a positive manner whether the malady had been measles or scarlatina. Similar cases have been observed by other practitioners.

Chronic Pericarditis.—A brief note of the following somewhat anomalous case may be found worthy of record. The patient, a man aged 60, was admitted to the Whitworth Hospital labouring under phlegmonoid erysipelas in both legs. He was in a very low asthenic condition, and required careful support and full stimulation, besides which repeated free incisions were made to give exit to large collections of purulent matter which formed at intervals in both lower extremities. Under this treatment the patient improved slowly, but when partially convalescent he was suddenly seized with an attack of vomiting at night, and threw up a considerable quantity of purulent matter mixed with blood. Extensive muco-crepitating râles were now audible through the anterior part of the left side of the chest, and sweats at night continued for a considerable period. No complaint was made of any symptom referrible to the heart, but in the course of a very careful clinical examination Dr. Lyons discovered the presence of an exceedingly well-marked double friction

sound of rough character in the præcordial region, audible over a space a couple of inches square, centering in the sternal attachment of the fifth left costal cartilage. The pulse was 140 per minute, and it may be mentioned that a marked atheromatous condition was observable in both radial arteries; in the right, about an inch and a half of the vessel presented a peculiar and regular moniform or minutely-beaded character sensible to the finger lightly passed over it; the left presented two or three somewhat sharp spicular elevations on being particularly prominent. The further details of this case may be shortly summarised. The patient convalesced gradually, acquired a very fair amount of health and strength, but two phenomena remained persistent during the many weeks he remained in hospital. The double pericardiac friction continued undiminished in intensity, but the patient was totally insensible of any pain, distress, or other symptom whatever referrible to the heart, and the pulse continued to range from 140 to 145. To this state the patient showed complete indifference, and having convalesced to his own satisfaction he insisted on leaving hospital, the cardiac sounds and pulse rate persisting as above described.

Acute Pericarditis, uncomplicated, latent throughout, fatal.—This case may be cited as an example of the extremely insidious and fatal character of pericarditis under certain circumstances. The patient, a girl aged 22, after exposure to cold winds, was found to exhibit acute pericarditis, under which she laboured for two days incessantly, and walked some distance to town. The pulse was 130, friction sound well marked, and no sense of pain complained of. The pulse rose day by day till it reached between 150 and 160, and, despite active treatment, she sank on the 8th day with symptoms of purulent absorption, the lymph exudation having become transformed into pus.

Cerebro-Spinal Arachnitis of about forty days' duration; recovery.—H. B., aged 22, a previously healthy young man, was admitted to the Hardwicke Hospital on May 13, 1866. His occupation, that of assistant in a mineral water manufactory, exposed him to a draught playing with some force through a gateway behind his back. He was somewhat suddenly seized on Friday, the 10th of May, the day of his attack, about three p.m., with pain in the neck and head. He at once came home and went to bed, and next morning found his neck quite stiff and painful and his head drawn back with inability to move it forward without inducing severe pain. The day following he was delirious, violent, and got out of bed, and could with difficulty be controlled and got back to bed. When seen after admission he was rational, but complained of violent pain in his head, which was retracted and could not be drawn forward without causing intense suffering, and in fact could not by any means be forced forward so as to perform the ordinary nodding motion. From this time forward his complaints had chiefly reference to his head, in which he suffered almost unremitting pain both day and night, much aggravated, however, during the latter interval, and over which remedies seemed to have but little control. Leeches were applied to the temples in repeated relays; in all, over twenty leeches were thus employed. The head was shaved and blistered, persistent attempts were made to bring his system under the influence of mercury, but without the smallest result; he was then treated with belladonna externally and internally. Three grains of the extract were ordered to be made into twelve pills, one to be taken every three hours; he took, in all, six grains of the extract, and he himself attributes more efficacy to this than to any other of the remedies employed, with the exception of the leeches, in which he had persistent faith throughout, and repeatedly when at his worst craved their renewed application. He was, it should be observed, carefully fed and his strength supported, and after the lapse of about three weeks a certain amendment was observable, the pulse sank to about 70, the rigidity of the deep muscles of the neck subsided, and he was enabled to nod his head forward with little or no pain. Intense pain in the head at night was, however, still the subject of con-

stant complaint, and a new and formidable symptom began to make its appearance. It was observed that the right pupil was slightly dilated, and slight impairment of vision in this eye was elicited on close cross-examination of the patient. The inequality of vision might have readily escaped notice but for the close surveillance that was maintained in regard to everything concerning so obscure and interesting a case. The impairment of the ciliary muscles was best evidenced by the following expedient adopted by Dr. Lyons to test the action of the iris. When the eye was covered with the hand for half a minute, and the pupil then allowed to dilate, it recovered its normal dimensions sensibly more slowly than that of the corresponding eye. This condition continued for a period of at least ten days, with persistent suffering from headache on the part of the patient, loss of sleep at night, and a state of things which promised but ill for any chance of ultimate recovery. Slowly, however, under the persistence of the treatment mentioned, the patient began to convalesce, the pupil gradually regained full power, headache diminished and finally ceased, and the patient is now convalescent. The total duration of the case was upwards of forty days.

The well-marked affinity with this case, that of a boy aged 12 years, in the same ward, may be mentioned. At a future period we trust to report a full history of his condition.

Syrup of the three Phosphates of Iron, Quinine, and Strychnia.

—At the suggestion of Dr. Lyons, Messrs. Graham have had made, by Serjeant Moss, two preparations of this combination. The stronger contains two grains, and the weaker one grain of the phosphate of iron, the latter more suitable for cases in which it is desired to administer the iron salt more sparingly.

Foreign Medical Literature.

TWO CASES OF TUMOUR OF THE BRAIN, WITH REMARKS ON THE CONNEXION BETWEEN CEREBRAL TUMOURS AND AFFECTIONS OF THE RETINA AND OF THE OPTIC NERVE.

By W. KOSTER.

Translated from the *Nederlandsch Archief voor Genees- en Natuurkunde*, 1e Deel, 4e Afl. Utrecht, 1865.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.,
HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE
NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY
OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURIS-
PRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

(Continued from page 658.)

b. *Echinococcus lobi postici hemispherii dextri. Syncope and convulsions. Blindness from inflammation of the optic nerve and retina.*

BOTHISIE V., aged 20, born at Heeg, in Friesland, presented herself on the 24th September, at the Netherlands Hospital for Diseases of the Eye, on account of great diminution of the power of vision. She had formerly enjoyed good sight. For the last six months the power of vision had gradually diminished, with such symptoms as violent headache, through the whole head, and great photopsia. For the last three months she has occasionally suffered on an average once in ten days, from attacks in which she falls powerless, without loss of consciousness.

She is a well-made person of middle height, pale complexion, her face is swollen; features quite devoid of expression. Her eyes are wide open, the pupils are large and little movable. The vision of the right eye is 2-200ths, of the left 10-200ths (that is, with the right eye letters can be distinguished at two feet, with the left at ten feet,

which the normal eye distinguishes at 200 feet). The field of vision is in both eyes very much limited concentrically. On examination with the ophthalmoscope the media are found to be quite transparent, but on the other hand there is considerable change of form of the papillæ nervi optici. These have quite lost their distinct boundary, coalesce in a diffused manner with the retina, which near the papilla is irregularly spotted and turbid, and are evidently swollen, their surfaces projecting more anteriorly than the other parts of the retina. Their colour is red, and in the erect as well as in the inverted image when strongly magnified, a number of radiating little vessels are distinguishable. The large vessels near the papilla are very tortuous, alternately dark and pale, the retina is here thick and irregularly transparent. In the yellow spot, especially in the right eye, a group of glittering white spots is perceptible, forming a bright white spot about equal in size to the yellow spot.

This form of neuritis n. optici was precisely that which occurs with tumours of the brain, as it has been repeatedly described by von Graefe. The peculiar attacks too confirmed the diagnosis of tumor cerebri. Syphilitic retinitis, or retinitis from Bright's disease, were also thought of. But from the history communicated by her medical attendant, it appeared that lues was out of the question, nor did any symptom exist indicative of it. The investigation respecting Bright's disease, to which the patient's appearance gave rise, was completely negative: no trace of albumen was found in the urine on repeated examination, neither did the other organs present any abnormality.

The patient was taken into hospital in order to be kept under observation. She was put upon treatment consisting in the employment of Autenrieth's ointment to the neck, and stimulating friction around the eyes; internally small doses of corrosive sublimate were given. In the attacks of violent headache cold water and sometimes ice were applied to the head. Thus she continued in hospital from the 24th September to the 17th October. During this time the power of vision diminished only slightly; she was, however, dull and depressed, and complained more and more of headache. The attacks of photopsia had not recurred; the papilla of the optic nerve was less red; the fits were more frequent and of longer duration; in them she fell down suddenly and appeared quite unconscious, although she subsequently said that she remembered very well what had happened to her; she was then put to bed and continued for some time oppressed with quick breathing, cyanotic colour and scarcely perceptible pulse. While she lay in bed, too, she was sometimes seized with an attack.

On the 17th October, the physician was called in the morning, because an attack appeared to last unusually long, and the respiration became quicker and shorter. When he arrived some moments later, she was already dead.

The post-mortem examination took place on the 18th of October, and, with the exception of the contents of the skull, no abnormality was found in any organ. The dura mater was loosely attached to the thin cranial bones. The convolutions of the upper surface of the brain were strongly compressed. The pia mater and the cerebral mass itself, however, contained a moderate quantity of blood; the parts at the base of the skull were normal, but appeared slightly flattened.

On the infero-posterior surface of the posterior lobe of the right cerebral hemisphere a swollen spot immediately caught the eye, in which fluctuation was perceptible, and where, moreover, fluid was distinctly visible through a very thin layer of the surface of the brain. The first impression was that a very high degree of hydrocephalus was present.

The cerebral mass was cut into layers at the under surface of the right posterior lobe, whereby we soon came upon a whitish tolerably resistant sac, surrounded by the white substance, but in the place already mentioned lying nearly at the surface. The cerebral mass was only loosely

connected with the upper surface of the sac, and could be detached from it with the handle of the scalpel.

The sac was cut into, and the fluid discharged was collected. The latter was clear as water; but in the portion which flowed out last a great number of white points were seen. The quantity of fluid thus collected amounted to upwards of 105 cubic centimètres. The nature of the new formation was at once evident from microscopical examination of one of the white corpuscles floating in the fluid: it consisted of a great number of well-marked *echinococci* loosely connected by a mucous mass.

On the inner wall of the sac great numbers of such round white corpuscles were seen to hang, as, after being separated, floated about in the fluid. Each of these collections of *echinococci* were from one-half to one and a half millimètres in diameter. The wall of the sac, subsequently dried and examined in sections, was rather more than a millimètre in thickness, and consisted of the ordinary multiple very firm layers, while internally the softer blastema layer occurred, from which, over the whole upper surface, the colonies of *echinococci* were developed.

Microscopical examination exhibited no other morbid constituents in the fluid. The chemical investigation was performed by Dr. Brondgeest. The fluid was clear, slightly viscid, had an alkaline reaction; its specific gravity was 1.0083, when evaporated at the temperature of 217° F., it left 1.5 per cent. of solid constituents. Neutralized with acetic acid it became rather turbid, and it yielded, when boiled with a trace of nitric acid, a flocculent precipitate; it was also precipitated by metallic salts and ferrocyanide of potassium when previously acidified (albuminous matters). An alkaline solution of copper was reduced by boiling; caustic potash and soda when boiled with it gave a brown colour (sugar). Boiling with chloride of iron gave rise to a brownish-red colour (succinic acid?). No cholesterine could be discovered.

The eyes and optic nerves were taken out, and were partly prepared for subsequent investigation, partly examined in the fresh state. From accidental circumstances, however, the examination was very imperfect.

The optic nerves, examined in sections taken both at the distance of the eye and in the neighbourhood of the sclerotic, both after being dried and after being hardened in chromic acid, exhibited no abnormality (Donders and Koster). The right eye was hardened in chromic acid, and exhibited on section a considerable swelling of the papilla of the optic nerve, passing equally on both sides into the surface of the retina. Some time later the retina was so brittle that no complete sections of it could be made. So far as they were obtained, it appeared that in front of the equator it was normal, and behind the equator it was here and there irregularly swollen, while precisely in that situation the elements of the different layers, the fibrous layer excepted, seemed less circumscribed.

A number of such sections, decolorised by soda, exhibited neither granular cells nor fatty metamorphosis. In the left eye, on the contrary, the examination of which was begun in the fresh state, a white coloration was seen at a distance of $3\frac{1}{2}$ millimètres from the papilla, which, brought under the microscope, exhibited on one side an imperfect, partly double circle of granule-cells, of about $1\frac{1}{2}$ millimètres in diameter, apparently situated deep under the surface. Issuing from the swollen papilla, the bundles of nerve fibres were seen with extraordinary distinctness spreading like a plexus on all sides; the fibres swollen, partly in a varicose, partly in a general manner, were easily isolated. The connective tissue was increased. The elements of the other layers exhibited also the larger and smaller bloodvessels, locally isolated, no abnormality. A portion of the retina was dried with the other membranes, and rather long after, it is true, was examined in sections. But that without the fibrous layer no extraordinary morbid changes existed, appeared satisfactorily, and in a hundred sections in different directions not a single granule-cell was seen. The changes seemed, therefore, to be restricted to the above-mentioned circle. In order to trace their situation

and their connexion to the elements of the retina, the preparation made, which was kept in glycerine acidified with acetic acid, was sacrificed. In this mode it was discovered that the granule-cells were situated under the fibrous layer, firmly enclosed in and difficult to be isolated from compact granules (most probably from the most external granular layer). To which elements of the retina their development was referrible could no longer with certainty be determined. The great firmness exhibited by the fibres of the fibrous layer in this preparation was remarkable. They suffered themselves, as it were, spontaneously to be isolated through a great extent, and exhibited in part a remarkable and extensive fusiform swelling, in part the ordinary varicosities. Of the half-dried membranes sections were also made, carried longitudinally through the optic nerve and the papilla: in this way a great increase of the connective tissue on the inside of the lamina perforata was seen, so that here between the nerve-bundles broad layers of connective tissue were continued, and moreover precisely in the place where the nerve-fibres lose their medullary sheath was a number of small granule-cells, only in the nerve-bundles, not in the intervening fasciculi of connective tissue. Transverse sections of the optic nerves dried, or hardened by chromic acid, exhibited no morbid changes.

The occurrence of a single *echinococcus*-sac in this case is remarkable. Nowhere else in the body, not even in the liver, were these entozoa met with. While we find *echinococci* comparatively frequently in the liver, they very rarely occur in the brain. In Lebert's "Anatomie pathologique" we find mention made of two cases, the one seen by him in the "Société d'anatomie" at Paris, the other quoted only as a case by Zéder. In addition, some scattered cases of *echinococcus cerebri* are known in literature.*

As the examination of the entozoa themselves afforded no new peculiarities worthy of note, we refrain from a detailed description of them. We should only repeat what is already to be found in the work of Lebert just quoted, particularly in Leuckart's well-known book,† and in many others. We believe, however, that we shall do the reader no disservice by taking this opportunity of briefly mentioning the facts at present known respecting the constitution and difference of the *echinococcus* colonies and the history of the development of these entozoa. The *echinococci* are found in two different sorts of cysts, of which the one is described as *scolecipariens*, and the other as *altricipariens* (Küchenmeister). The latter consists of a smaller or larger cyst, on whose inner wall a gelatinous formative layer containing granules occurs, which in different places gives origin to fresh *echinococcus* colonies. Of this our case consequently presents a type. The whole internal surface was studded with adherent points, each consisting of ten, twenty, and more distinct animalcules, in various degrees of development. A process of the formative layer keeps the animalcules together, even after they have become quite independent, and no longer adhere to others, from which they sprang by germination. Finally, they become more free from the formative layer, are connected only by a little stalk to the whole colony, and may then fall off into the fluid which fills the large mother cyst; or the entire collection of more fully developed *echinococci* falls off from the wall, and forms the corpuscles floating in the fluid, such as were found especially in our case. The mode of development seemed in all points to agree perfectly with the complete and accurate description given by Leuckart, to which I would therefore refer the reader for further particulars.

The *Echinococcus scolecipariens* (*Echinococcus veterinorum* of earlier writers), which is found chiefly in the

* Hooper, *Morbid Anatomy of the Human Brain*. Küchenmeister, *Schmidt's Jahrbücher*, Bd. 99, p. 99, et seq. G. Rodust in Henle und Pfeufer's *Zeitschrift*, Bd. xv., Hft. 3.

† *Die Menschlichen Parasiten, und die von Ihnen herrührenden Krankheiten* [Human Parasites, and the diseases proceeding from them], p. 328.

liver, is distinguished by this, that from the original hydatid germs do not arise on the inner wall, but fresh echinococcus sacs form close to it, so that at last an infinite number of sacs of various sizes lie close to one another. The mode in which this process takes place has not yet been cleared up in all its parts, but it depends evidently on a proliferation outwards from the original cyst, and partial separation. The occurrence of such a colony may, as the cysts are very small, give rise to their being mistaken for alveolar canceroid.*

The history of the development of echinococci was cleared up by the experiments of von Siebold.† The reason why the tapeworm, which is formed from the hydatid, was so long overlooked, lies in the smallness of the animal.

The latter consists of only three or four articulations, of which the last, in the mature state, is larger than the remainder of the animal, which, in its integrity, is only four millimètres long. The animalcule is met with in the intestinal canal of the dog, and the ova are apt to occur in the intestinal canal of cattle, apes, and men,‡ in whose stomachs the development of the scolex begins, which, after a longer or shorter journey through the body, settles somewhere permanently, and by external proliferation (echinococcus scolecipariens), or by germination taking place on the inner wall (echinococcus altricipariens), is developed into a colony, by preference in the liver or brain.

The patient observed by us belonged to the peasant-class; the ingestion of eggs of a tænia echinococcus (probably from ditch-water) might, therefore, easily take place. We can thus readily understand the intrusion of the echinococcus-scolex in him, although we must, of course, refrain from an endeavour to explain the further development in this case, precisely in the posterior lobe of the right hemisphere of the brain.

The scolex thence penetrated prejudicially, and, by gradually developing the large cyst, gave rise to irritation of and pressure on the brain. As to the comparative slightness of the persistent phenomena of cerebral affection, the irregularly recurring attacks of syncope and spasms, and the manner in which at length death ensued, we must be silent. Our very slight knowledge of the signification of the parts of the brain and of their functions, of the periodicity of the phenomena of nervous action, even in the normal state, and of the connexion between organic changes within the skull and disturbances in the cerebral function, is in such a case again distinctly illustrated, placing the history we have recorded in the same category with so many observations of cerebral abscesses and tumours of the brain, which sometimes betray themselves only by headache, slowness of movement, and slight dulness of intellect, and in which death suddenly ensues.

In this case we have not even the possible explanation of the fatal result by supervening cerebral congestion, effusion, hæmorrhage, which might hold good in the first case. The proofs of such lesions did not exist in this second case.

(To be continued.)

‡ The frequent occurrence of echinococci among the inhabitants of Iceland, where, according to Eschricht, about one-sixth of the population dies of the affection, depends on their living in close contact with their numerous dogs.

THE doctrine of the conservation of force seems to have met with an opponent in Professor William Thomson, who has delivered the annual Rede Lecture at Cambridge, taking for his text "The Dissipation of Energy." He is stated to have arrived at the conclusion that the earth is again approaching, by the gradual dissipation of energy, a state resembling its primal condition, and in which it will be as it had been, inhabitable by man as at present constituted.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MAY 2ND, 1866.

Dr. BARNES, President.

THE following gentlemen were elected Fellows:—Dr. Andrews; Dr. Rugg; Mr. Sequire and Mr. Bassett of Birmingham; Mr. Blease of Altringham; Mr. Brown of Ealing; and Mr. Cornwall of Fairford. Professor Lazarévitch of Charkoff, was elected an honorary Fellow of the Society.

Dr. WILTSHIRE showed a new form of Uterine Tent, composed of sponge and laminaria, the sponge forming an outer casing to the laminaria.

Dr. BARNES exhibited a Uterus with its Appendages which were affected with colloid disease. He also showed a specimen, which he had received from Dr. Brunton, of Abscess in the Placenta. The abscess contained about an ounce of pus. There had been no symptoms of pain during gestation; but there had evidently been inflammation of the decidua. Dr. Barnes considered these cases very rare, and exceedingly interesting. He knew of but two or three on record, and they were described by French authors.

CASES OF LACERATION OF THE UTERUS, WITH REMARKS.

By THOMAS RADFORD, M.D.

The author, after briefly alluding to the views of Hunter, Denman, and Douglass on this most dangerous complication to labour, related minutely the histories of nineteen cases which had fallen under his notice. Of this number, in eleven the ages registered were from twenty-one to forty years, and it was found that the accident occurred more frequently between the ages of thirty-nine and forty. The number of labours which each woman had undergone varied from the first to the eleventh; and it was shown that laceration of the uterus happened most frequently in women pregnant for the eighth time, and that in those *enccinte* for the first time the accident took place quite as often as it did in any of the other cases which were registered. The duration of the labour from its commencement to the occurrence of laceration (though in some cases not exceeding three or four hours) was generally from ten to thirty hours. Of the various causes or conditions mentioned as producing laceration, slight contraction at the brim of the pelvis appeared to have been the most frequent. The author considered that when the form of the pelvis was only slightly contracted, the os and cervix uteri partially descended during labour into or a little through the aperture of the pelvis, so that, as the head of the infant was forced down, the uterine tissues became fixed between this body and the pelvic bones. The fixity of this structure actually formed a *point d'appui* from which the uterine fibres during contraction forcibly pulled; and the great probability was that sooner or later the tissue either directly tore, or, being first contused and softened, yielded. As regarded the situation of the laceration, the cervix uteri was the part most frequently affected, and sometimes with it the body of the organ was also implicated. In eleven cases the laceration was longitudinal, in three transverse, in three oblique, and in one circular. Of the nineteen cases, three recoveries took place, or nearly sixteen or seventeen per cent. Dr. Radford, in his concluding remarks, observed that when we contemplated the frequent fatality of laceration of the womb, we were led to inquire whether there were no symptoms which showed themselves as universal precursors of this dreadful catastrophe; and if there were, were we possessed of the means of prevention. In all the cases he now brought before the Society, there could not be found any with premonitory symptoms which of themselves

would warrant any operative measures being taken in order to avert the impending danger. Nevertheless, he thought we should carefully consider all the contingent circumstances of protracted labours, and especially of those which were prolonged by mechanical impediments; and whether they were produced by relative disproportion of the capacity of the pelvis to the size of the foetal head; if so, we should adopt measures of timely delivery.

Dr. GRAILLY HEWITT acknowledged the great value of Dr. Radford's paper, but could not agree in the antiphlogistic treatment mentioned by the author. He (Dr. Hewitt) concurred in the opinion that there was an absence of uniformity of symptoms in these cases; and strongly urged the necessity for early artificial aid in some cases of protracted labour. He related a case of concealed hæmorrhage, in which the symptoms were closely allied to those observed in ruptured uterus.

Dr. PLAYFAIR could not approve of the treatment which had been adopted in those cases where the fœtus had escaped into the peritoneal cavity. He thought a much better line of treatment would be to perform gastrotomy. He knew of twelve cases in which this operation had been performed, and in some with satisfactory results.

Dr. BRAXTON HICKS said that, with respect to the symptoms of rupture, it was generally asserted that recession of the head was a constant symptom, but that he had never seen a case where this had taken place. He believed there were many more cases of ruptured uteri than we were cognisant of. Dr. Hicks believed that one of the greatest safeguards against rupture was the use of chloroform.

Dr. EASTLAKE observed that in the diagnosis of rupture of the uterus some data were furnished by auscultation, the foetal heart sounds becoming inaudible after the rupture. This point Dr. McClintock strongly insists upon; as also that in these cases there is very little hæmorrhage.

The PRESIDENT regretted that through indisposition Dr. Radford was unable to be present. He considered the first great cause of rupture was protracted labour, and the object to be had in view was to remove the obstruction as speedily as possible. A second cause was rigidity of the os uteri, and he agreed with the author as to the necessity of incising the os. A third and fourth cause existed in the obliquity of the uterus, which caused it to become jammed in the pelvis; also, when there is a dead fœtus in utero there is a want of the resiliency which a live child possesses, and the action of the uterus rather tends to squash than to expel it. He also mentioned disease of the uterine tissue as another cause leading to rupture. He thought softening of the tissue might depend upon degeneration, either before labour or during labour, by the pressure of the foetal head against the pelvis. With respect to gastrotomy, he would say that Dr. Radford had urged the operation, but that it had been overruled by others. The late President of the Society objected to any operative measures whatever when the fœtus had escaped into the abdominal cavity; and he (Dr. Barnes) had seen a case where it was left, and the woman recovered.

Dr. BRUNTON observed that the cases which Dr. Radford had collected were attended by midwives, and he knew that midwives were in the habit of giving very large doses of ergot. He believed that this was one of the great causes of rupture of the uterus; and when it did not cause rupture the placenta was often retained, owing to the irregular contractions of the uterus produced by that drug.

The meeting then adjourned.

ROYAL COLLEGE OF SURGEONS IN ENGLAND.—During the last week nearly one hundred and thirty gentlemen have been undergoing the preliminary examination in Arts for the Fellowship and Membership of the College; for the former distinction, however, only sixteen candidates offered themselves. The result of these examination will not be known for a week or two.

Abstracts of the Scientific Societies.

ROYAL.—May 31.—Dr. W. A. Miller, Treas. and V.P., in the chair.—The following papers were read: "An Account of certain Experiments in some of which Electroscopic Indications of Animal Electricity were detected for the First Time by a New Method of Experimenting," by Dr. C. B. Radeliffe.—"On the Stability of Domes," by Mr. F. W. Tarn.—"On the Means of Increasing the Quantity of Electricity given by Induction Machines," by the Rev. Dr. Robinson.—"On the Dynamical theory of Gases," by Mr. J. C. Maxwell.

GEOGRAPHICAL.—June 11.—Sir R. I. Murchison, Bart., President, in the chair.—"On the Effects of the Destruction of Forests in the Western Ghats of India on the Water Supply," by Mr. C. R. Markham.—"On Mediæval Travellers to Cathay," by Col. H. Yule. The author had for some time past made a special study of all the accessible materials relating to travels into China during the thirteenth, fourteenth, and fifteenth centuries, and the paper was a summary of the results of his researches. Travellers at this period entered China from the side of Tartary; and as the country was called in this part of Asia *Khitai*, it became known in Europe by the name of Cathay, a word of nearly the same pronunciation. The travels of Marco Polo were passed over as already well known, and the author dwelt at more length on the journeys of Friar Odoric, Ibn Batuta, and John Marignolli, the Papal Legate of 1338; the journals of the last-mentioned not having before been made known in England.

GEOLOGICAL.—June 6.—The following communications were read: "On the Metamorphic and Fossiliferous Rocks of the county of Galway," by Prof. R. Murchison.—"On the Metamorphic Lower Silurian Rocks of Carrick, Ayrshire," by Mr. J. Geikie.—"On a Cheirotherian Footprint from the base of the Keuper Sandstone of Darsbury, Cheshire," by Mr. W. C. Williamson.—"A description of some remarkable 'Heaves' or Throws in Penhalls Mine," by Mr. J. W. Pike.

LINNEAN.—June 7.—"On Myostoma, a new Genus of Burmanniaceæ," by Mr. J. Miers.—"On two new Genera of Compositæ (Mutisiaceæ) from India," by Dr. Thompson.—"Notes on the New Zealand Siliçæ," and "Observations on New Zealand Lichens," by Dr. W. L. Lindsay.—"On the Surface-Fauna of Mid-Ocean—No. 2. Foraminifera," by Major S. R. J. Owen.—"Characters of some undescribed Heterocerous Lepidoptera," by Mr. F. Walker.

ENTOMOLOGICAL.—June 4.—Sir J. Lubbock, Bart., President, in the chair.—Prof. Brayley communicated an extract from the Report of Mr. Consul Zohrab on the trade of Beldiansk for 1865 (received at the Foreign Office, and recently presented to Parliament), respecting a poisonous black spider which had appeared amongst the wheat at harvest time, had bitten more than three hundred persons, and created such a panic among the labourers that wages rose to double their ordinary rate.—Mr. McLachlan exhibited a caddis-worm case, of the genus *Linnæophilus*, containing a dead pupa; the caddis-worm had, as usual, attached itself to a rush before changing to the pupa state, but had failed to make proper allowance for the growth of the rush, by which the case had been raised a couple of feet above the surface of the water, and the pupa had died in consequence.—Mr. Stainton mentioned that the gall-making larvæ on *Gypsophila saxifraga*, from Mentone, which he had exhibited at the previous meeting, had produced a species of *Gelechia*, allied to *G. leucomelanella*.—Mr. Pascoe exhibited a small collection of interesting Coleoptera, received by the Rev. H. Clark from the Rev. G. Bostock of Fremantle, Western Australia, including two new species of *Articerus*, an entirely new form, perhaps belonging to the *Pausidæ*, or perhaps more nearly related to *Gnostus*, and of which a description was read under the name of *Ectrephes formicarum*; also several specimens of *Anthicus* found in ants' nests, and other novelties belonging to the genera *Prinus*, *Hyocis*, *Platynotus*, *Mecynotarsus*, &c.—Prof. Westwood exhibited drawings and read descriptions of various new species of Goliath beetles.—Mr. C. A. Wilson communicated a further instalment of his "Notes on the Buprestidae of South Australia."

Reviews.

ON THE FUNCTION OF ARTICULATE SPEECH, AND ON ITS CONNEXION WITH THE MIND AND THE BODILY ORGANS: illustrated by a reference to recent Observations on Certain Diseased States of the Brain. By W. T. GAIRDNER, M.D., Professor of Practice of Physic in the University of Glasgow. Glasgow. 8vo. 1866.

THIS is an 8vo pamphlet of thirty-nine pages, chiefly consisting of a paper under the above title, which was read before the Philosophical Society of Glasgow on the 7th of March in the present year. In addition to this paper, however, Dr. Gairdner gives us a case of aphasia which occurred under his care, and was subsequently published in the *Glasgow Medical Journal* for May, 1866; from that journal it is now reprinted. The attention of the profession has been of late years aroused to the minute consideration of this interesting affection, perhaps more by the writings of M. Trousseau than by those of any other prominent member of the profession. The result has been that numbers of our best educated physicians have directed their attention to the subject; and here we may remark, *passim*, that no inquiry that we are aware of so strongly tends to show the advantage of a good education to a physician as this one does; and, if we be not greatly mistaken, papers, such as that of Dr. Gairdner, will very much advance the interests of our calling as a *learned* profession; for this subject concerns divines, lawyers, philosophers, and literary men, as well as ourselves. As an instance in point, we may call attention to a report of cases which have lately occurred in Mercer's Hospital, under the care of Dr. Moore, a Dublin physician, and which we have much pleasure in presenting to our readers in our number of this day. The limits of a notice of this kind forbid a general discussion of this subject, so that we can only refer to a few points in Dr. Gairdner's paper. He considers:—

"That the devising of some form of speech must have been one of the first acts of the essentially human free will; and further, that the first effort of speech beyond a mere inarticulate cry, must have been the mental discrimination, and afterwards the designation, or *naming* of objects differing from that which is possible, even after ages of education by the side of man, to the dog, the horse, or the elephant, or even to our quadrumanous cousin (as some will have him) the ape, with his wonderful mimicry of the lower attributes of humanity."

Dr. Gairdner, after referring to a discussion on this subject in the French Academy of Medicine, to MM. Auburtin and Broca, and to M. Trousseau's researches, to the history of the term *aphasia*, and to a paper by Dr. Sanders in the *Edinburgh Medical Journal* for March, 1866 proceeds to detail and analyze some cases of this affection which occurred in his own practice and in that of other physicians. Like other writers, Dr. Gairdner notes the curious fact, that when the general faculty of speech is impaired, and when the articulation of ordinary language is all but destroyed, the power of uttering curses and oaths seems to hold its ground in no small degree.

There is much in this paper that is interesting, but it seems to us to be defective in two important particulars:—1. It omits to mention that the subject is by no means a new one; and, 2, it in no way acknowledges the labours and writings of the Dublin School, some of these writings having appeared probably before Dr. Gairdner was born. In a *literary* question, such as this is, these are capital defects; and now that they are pointed out, we are quite sure Dr. Gairdner will remedy them in his next paper on aphasia.

The late Dr. Osborne, one of the most learned physicians who ever wore a scarlet gown in Dublin, published in the year 1834, a most curious paper, "On the Loss of the

Faculty of Speech depending on Forgetfulness of the Art of using the Vocal Organs." This appeared in the fourth volume of the *Dublin Medical Journal*. In the year 1845, Dr. Steele, of Dublin, published in the January number of the same journal "A Case of Loss of Speech, &c., with Observations." This paper is well worth reading, especially that part which relates to the *faculty* of speech, as an essentially human endowment. In the *Dublin Quarterly Journal of Medical Science* for February, 1865, Professor Banks published a long essay "On the Loss of Language in Cerebral Disease." This essay contains, in fact, a review of the literature of the whole subject, and makes frequent references to papers written by Graves, and to the writings of Forbes Winslow, as well as to the experience of Dr. Banks himself, and to that of Dr. Kidd, with whom he saw one very curious case.

The extraordinary retention of the power of cursing and swearing was noted in "A short Biographical Sketch of a Remarkable Case of Insanity," published by Dr. Belcher in the *Dublin Quarterly Journal* for 1864; and in our own *Hospital Reports* for May 23, 1866, we published the details of "A Remarkable Case of Softening of the left Anterior Lobe of the Cerebrum, with Right Hemiplegia, and Loss of Speech," which occurred under the care of Dr. Hayden at the Mater Misericordiae Hospital. Dr. Moore's cases continue the series.

ON THE APPLICATION OF SULPHURIC ACID GAS TO THE PREVENTION, LIMITATION, AND CURE OF CONTAGIOUS DISEASES. By JAMES DEWAR, M.D., Kirkecaldy. Pp. 31. Edinburgh: Edmonstone and Douglas. 1866.

DR. DEWAR instituted a number of experiments with sulphur fumigation in connexion with the cattle plague, and he informs us that the plan has been very successful as a prophylactic. He has extended the same mode of treatment to the human subject, and the results are very encouraging. He relates several cases of phthisis in which the symptoms have been mitigated by the fumigation, and he also tells us that some diphtheritic cases have been cured by the same means. Dr. A. Halliday Douglas of Edinburgh, has been so much struck with the results that he has caused a chamber to be constructed for sulphur fumigations in an hospital with which he is connected, with a view of testing further the powers of this treatment in pulmonary complaints.

A VISIT TO VICHY, comprising a Sketch of its Mineral Springs and Thermal Establishment, with a Notice of the Medicinal Uses of the Vichy Waters, Salts, &c. By M. PROSSER JAMES, M.D., Senior Physician to the City Dispensary, &c. Pp. 50. London: Williams and Co. 1866.

THE waters of Vichy have now a world-wide reputation, and their efficacy in certain classes of diseases is indubitable. As is well known, they contain a large quantity of bicarbonate of soda with free carbonic acid, and although it would appear from chemical reasoning that they must be less adapted for remedying the uric acid diathesis than waters containing potash, yet the Vichy Springs are visited by multitudes of invalids every year, and the waters are carried away to be consumed in distant lands by those who cannot make the journey to the place itself. Dr. James' pamphlet contains a great amount of useful and amusing information in relation to Vichy, its history, its scenery, and its springs, and he gives a list of diseases in which the waters have been used with advantage.

THE TRUE AND FALSE SCIENCES: A Letter on Homeopathy. Pp. 40. London: Churchill and Sons. 1866.

At a period like the present, when it would appear as if a kind of universal scepticism had seized upon the minds of

men in most subjects, and especially in matters relating to medicine, it is indeed extraordinary that the dogmatic absurdities of the so-called homœopathic system should obtain even a momentary attention. One theory on which the system rests, namely, *similia similibus*, &c., being untrue in fact, and the other, namely, the efficacy of medicines in the inverse proportion to their quantities, being at variance with the laws of nature, homœopathy, as a science, has no foundation at all, and the best that can be said of it is that the homœopathic globules, if honestly administered, do no harm, and that in many cases the patient gets well by the unaided powers of nature. The author of this pamphlet puts the whole question of homœopathy before the reader in a very sensible, calm, and dispassionate light. He appears to be well acquainted with the principles of Hahnemann and his disciples, and with regard to Hahnemann himself, he has come to the conclusion, with which we are inclined to believe most rational people will agree, that he was neither a fool nor a knave, but a solemn fanatic, unendowed with the sense of the ludicrous, and therefore unable to appreciate the folly of his own speculations.

THERMOMETRIC OBSERVATIONS ON THE FEVERS OF CHILDREN. By G. STEVENSON SMITH, L.R.C.S.E., &c. Edinburgh. 1866.

THIS is an 8vo pamphlet of twelve pages, and is a reprint from the *Edinburgh Medical Journal* for March, 1866. It treats of "The Normal Standard of the Temperature in Children as compared with that of Adults; of 'The Value of the Thermometer as a Diagnostic Agent;'" and gives tabular thermometric registries in cases of typhus, typhoid, and scarlatina.

The use of the thermometer as a diagnostic agent in disease is steadily making its way, and this paper tends to explain and simplify its use in some of the most fatal diseases of childhood. We hope its writer will continue his observations.

THE EDINBURGH MEDICAL JOURNAL FOR JUNE, 1866.

THE present number contains the usual amount of useful and interesting papers.

We may particularly note one, the Harveian Discourse on the Life and Character of Dr. Alison; and we only wish that medical biographies were more frequently put before reading men in our profession. The other original communications are:—A paper on Paracentesis Thoracis in Pleural Effusions by the well-known Dr. Warburton Begbie; one on the Convolutions of the Human Brain, topographically considered, by Mr. Wm. Turner; two cases of Purpura Hæmorrhagica in Children, with remarks, by Mr. Stevenson Smith; and one on Dilatation of the Perinæum, by Dr. James More of Rothwell, Northamptonshire.

THE SOCIAL SCIENCE REVIEW. SANITARY REVIEW, AND JOURNAL OF THE SCIENCES, June, 1866.

THE present number is much above the average in point of interest; and is peculiarly attractive to medical readers, as four out of its six original papers concern us: I. is on the Prevention of Infection; IV. on Hospitals, their dimensions, site, construction, airing, warming, and ventilation; V. on Inevitable Diseases; and VI. a Memoir of Dr. Thomas Hodgkin. The remaining papers are also interesting to us as subjects of the British Crown; II. is headed, "Analysis and Description of the Report of the Royal Commission on Capital Punishment, 1866;" and III. is on a very important matter, "The Redemption of the National Debt."

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 27, 1866.

THE PERILS OF HOSPITAL PRACTICE.

AN action of what the *Times* calls "a rather novel character," was tried before the Lord Chief Justice in the Court of Queen's Bench a few days ago. If we were to designate the action we should style it as an instance of the astounding abuse to which the law may be put in persecuting persons of position and respectability, because they happen to belong to the Medical Profession. The plaintiff is a Polish tailor, and the defendants, on this occasion, are not private practitioners pursuing their profession for the ordinary purpose of remuneration, but they are Mr. TIMOTHY HOLMES, the distinguished scholar, author, and surgeon, who, as Assistant-Surgeon to St. George's Hospital, was temporarily performing the duties of Mr. TATUM, one of the Chief Surgeons; and Mr. FREEMAN, the House-Surgeon of the same institution. In the quaint and technical language of the "declaration" in which the plaintiff set forth his grievances, it is stated that he "retained and employed the defendants, to bestow their care, skill, diligence, and attention, as and in the way of their profession and business of surgeons and apothecaries, in and about the treatment of the plaintiff, for and in respect of a certain complaint and disorder, and that the defendants accepted and entered upon such employment, but conducted themselves so carelessly and unskilfully in and about the treatment of the plaintiff, that by reason thereof the plaintiff was wrongfully placed and immersed and forcibly held in a bath heated to an excessively and improperly high temperature, and for an excessive and improper length of time, whereby the plaintiff was severely scalded, wounded, and injured."

Now, those who are acquainted with the documents known as "declarations" need scarcely be informed that they may or may not be a tissue of falsehoods; but the usage of the law permits and even encourages the exaggerated, not to say mendacious language which they contain, the only reparation made to the person against whom they are levelled being that the charges are abandoned when they cannot be proved in evidence. How far the declaration of grievances sustained by the plaintiff in the case to which we allude is a veracious statement must be judged by those who follow the course of the proceedings. We may state generally that, whether the statements contained in a declaration be true or not, a great deal of money is expended on both sides, first of all in clearing away the legal cobwebs in which the case is always and purposely involved, and then in eliminating whatever grains of fact may be contained amidst the superfluity of verbosity, exaggeration, or downright lying, which the ingenuity or the imaginative powers of some members of the legal profession may construct.

THE Poor-law Medical Officers in London have formed themselves into an Association.

It is well also for every member of the Medical Profession to recollect that in almost every act which he performs, or, indeed, we might say in every trifle which he may neglect to perform, in the daily and hourly routine of his avocations, he is liable to have an action at law levelled against him, his only protection being his inability to pay the expenses of a heavy lawsuit. It is very rare, indeed, for these actions to be brought against such unfortunate members of our Profession as may be struggling with difficulties, and if any of our brethren should unhappily have been bankrupt or insolvent, or have been known to compound with their creditors, they may have the satisfaction, however melancholy a one it may be, of knowing that they are at least secure against these frivolous lawsuits which the rapacity of attorneys may suggest, and which our courts of law, by a perversion of the noble principles which they were originally designed to uphold, are always ready to entertain. Thus every member of our profession in every step or transaction of his ordinary avocations, has a kind of sword of DAMOCLES suspended over his head, and the more respectable he is the more probable it is that the blow will be aimed against him. For it cannot but happen, considering the fallacy of human judgment in general, and the peculiar difficulties besetting the art and practice of Medicine and Surgery in particular, that the results of cases will often disappoint expectation, or even that errors of judgment may be committed; but against the consequences of such mishaps or misadventures in most other professions, custom and prescription and law itself have carefully guarded the individual agent. Thus a clergyman, for instance, may be betrayed into the enunciation of erroneous doctrines, but his fault is cognisable only before the tribunal of his ecclesiastical superiors; a magistrate may commit an innocent person to gaol on erroneous evidence, but he is legally exempt from all consequences unless he has been actuated by corrupt motives, and a lawyer may utter as many libels as he pleases, perhaps to the ruin of the person attacked, if only they are uttered in a Court of Justice.

But to allude more particularly to the case which has called forth these remarks, we must observe that in all other cases of a similar kind the surgeon has been called to account for some malpraxis or negligence, real or assumed, committed by himself, but in the action against MESSRS. HOLMES and FREEMAN the defendants are actually made the victims for an injury, which, if it ever was inflicted at all, was the act of persons who were not even their servants but the officials of a public institution!

We have given an abstract of the trial in another column, and are therefore relieved from the necessity of commenting upon the evidence in detail, and we only remark that in point of law the plaintiff had not a leg to stand upon as against MESSRS. FREEMAN and HOLMES. If any injury was inflicted it was by the fault of the nurses, against whom or against the Hospital authorities

the action ought to have been brought, if it were brought at all. But it appears that the Hospital was applied to by the legal advisers of the plaintiff, and that the Governors were willing to make any reasonable compensation if the plaintiff could prove that he had sustained any injury, and if he would forego an action at law. But, acting either on his own judgment, or on the advice of others, he chose to bring his action, the result of which will be that he will not only receive nothing at all in the way of compensation, but will have to pay all the expenses of the cause into the bargain. It is stated that MESSRS. HOLMES and FREEMAN will not be put to any personal expense in the proceedings, as the cost of the defence is defrayed by the Hospital.

THE USES OF SULPHUROUS ACID GAS.

FOR many months Dr. DEWAR of Kirkcaldy, has been engaged in impressing upon the Government, the public, and the profession, the importance of employing the fumes of sulphur in the prevention and cure of disease, and quite recently he has extended their use in a different and scarcely less important direction—the preservation of animal food. Without accepting his views of the nature of disease—pointing, as he seems to indicate, to the origin of all disease from cryptogamic spores—as at all correct, we may nevertheless state that he has arrived at several interesting and remarkable practical results. Dr. DEWAR's experiments were at first initiated in connexion with cattle plague, and his method of fumigating byres is to take a chaffer two-thirds full of red cinders, place a crucible in them, and in it a piece of sulphur stick the length of one's thumb, which is sufficient for a byre containing six cattle. If ordinary attention be paid to ventilation, the attendant may shut himself in along with the cattle during the process, not only without detriment, but, as we shall presently see, with occasionally unlooked-for benefit. This process may be repeated four times a day, and the result has been that, when this system has been thoroughly and determinedly practised, there has been no case of death among the cattle from any epidemic cause whatever. Nor has this been the sole result. Ringworm, angle-berries (molluscum), mange, and lice have disappeared, and a horse which had been a few times unintentionally fumigated, was unexpectedly cured of obstinate grease of the heels. Nay more, in a large dairy, which for thirty years had maintained a notorious character for mortality from pleuropneumonia, and the present tenant of which had for eight years past never been one whole month free from this disease amongst his cattle up to the 1st November last, and had buried sixteen cows during the preceding twelve months, the last of them only three days before he began to fumigate, this disease has since then ceased to be observed, and the cows have remained perfectly healthy. These facts are extremely remarkable, and of themselves would compel a further investigation of the influence of sulphurous acid fumes; but what we have still to relate is still more extraordinary, and could scarcely be believed but upon the testimony of an upright and honourable medical man, such as we know Dr. DEWAR to be. For not only were chilblains and chapped hands found to disappear from the hands of the attendants upon those cattle which were regularly fumigated, but in the case of a groom of Dr. DEWAR, supposed to be dying from phthisis, and who was

employed to fumigate certain cattle, the most extraordinary results were attained; for within one week the night sweats had ceased, his cough gradually abated, the expectoration diminished, and he gained nearly two stones within four months, and though now dependent for existence upon one lung or little more, he looks nearly as strong and is as able for ordinary stable-work as he was previous to his illness.

This case has been observed by Professor Sir J. Y. SIMPSON, by Dr. HALLIDAY DOUGLAS, and by other medical men, who are conversant with the facts. Indeed, so remarkable and encouraging have the results obtained in this and in several other similar cases appeared to Dr. HALLIDAY DOUGLAS, that he has determined to construct a chamber for the purpose of employing sulphur fumigation in connexion with the Chalmers Hospital, that he may have an opportunity of personally investigating the matter and testing the results. It is truly somewhat singular, and peculiarly illustrative of the circular—or shall we rather say spiral—manner in which medicine moves, or, if you will, progresses, though its progression is limited, and as yet not well defined, that HAHNEMANN was led by his theory of disease to propound sulphur as the most important remedy in tuberculosis, while Dr. DEWAR, from the success of sulphur in its treatment, has been apparently led to deduce its origin from cryptogamic spores—a closely similar theory. With theories, however, there is at present no need of troubling ourselves; the practical results are sufficiently striking to insure for this treatment a more careful and extensive trial. In diphtheria and various other complaints sulphur fumigation has proved immediately and strikingly beneficial, and in at least one instance it has almost instantly cut short an outbreak of hospital gangrene in the wards of our Edinburgh Infirmary, and, properly employed, it may possibly prove capable of limiting the spread of cholera, fever, and other contagious diseases. For the disinfection of inanimate material the addition of a little nitre to the sulphur, and the combination of these fumes with the steam of boiling water, improvises a disinfectant at once the most powerful, most searching, and most efficacious which can be obtained, utterly destructive at once of any latent contagion, and of every form of insect life. But we have not yet exhausted all the strange properties of sulphur fumigations: it is not only productive of animal health while in life, but it also prevents putrefaction after death. In some recent experiments (in June weather) in regard to this, a sheep's head was kept quite fresh and sweet for thirteen days; a boiled crab—well known to be a peculiarly perishable edible—was quite sound after eight days; haddocks, after being smoked two or three times, were found to be quite fresh at the end of eight days. The process is equally applicable to every other form of animal food, which merely requires to be fumigated three or four times a day in a chamber closed as much as possible against the admission of fresh air. At a convivial entertainment recently given by Dr. DEWAR the company were entertained with viands thus preserved, and one and all expressed their perfect satisfaction with the success of the process, as evinced by the satisfactory condition of the food presented to them.

How novel and strictly original Dr. DEWAR's views are as to the pleasantly tonic virtues of sulphur fumigations may be learned from a statement in the most recent work on materia medica—Dr. SCORESBY-JACKSON'S "Note-Book"—where he states that in sulphur fumigations "great

care must be taken to protect the respiratory organs from the fumes by closing the apparatus round the neck, and yet how inconsistent these ordinary views are with popular experience may be learned from the popular idea of the great benefit to be derived from new flannel—that is, flannel thoroughly impregnated with sulphur fumes, and also with the fact that in woollen mills—in certain departments of them—the workmen live from year's end to year's end in an atmosphere thoroughly impregnated with sulphurous acid gas. Unquestionably a laborious and tedious accumulation of experience in regard to the positive influence of sulphur fumes upon the health may be anticipated by an inquiry into the ordinary condition of such workmen; and we shall feel obliged if any of our readers shall be kind enough to contribute any information on this head, similar to that which was contributed to the *Monthly Journal* by Dr. THOMSON of Perth, in regard to the influence of an atmosphere charged with oil. It would indeed prove singular if, after all, the benefit supposed to be derived from oil was solely due to sulphur.

THE MORISON LECTURES, EDINBURGH.

THE six Annual Lectures on Mental Diseases, under the late Sir ALEXANDER MORISON'S endowment, are now being given in the Physicians' Hall, Queen-street, by Dr. SELLER, the able and accomplished physician specially appointed by Sir ALEXANDER MORISON to be the first lecturer under this endowment.

On each succeeding Tuesday and Thursday the hall is well filled with an audience, comprising not only the *élite* of our Edinburgh medical men and many of our brethren from the country, but also many members of the legal profession, not of its subordinate branches only, though these are well represented, but even from the Bench itself.

The first lecture, which was delivered upon Tuesday, the 5th of June, was chiefly occupied by a rapid sketch of the life and labours of the late Sir ALEXANDER MORISON, and in particular with an account of the few months immediately preceding his death, which took place at his house near Balerno, in the parish of Currie, at the advanced age of 87. The latter portion of the lecture was occupied by a sketch of some of the medical aspects of deprivation of mind.

The second lecture of this course, which was delivered upon Thursday, the 7th of June, was occupied with a detail of some of the legal aspects of deprivation of mind. The third lecture, delivered on the 12th of June, took a rapid survey of some of the social aspects of deprivation of mind, special attention being directed to so-called "judicial murder" in relation to the case of persons supposed to be insane, and to the actual and intended influence of capital punishment, as well as to the equally interesting and difficult subject of the legal restriction of drunkards. The fourth lecture, delivered on the 14th of June, entered in a most interesting manner into the subject of deprivation of mind in relation to the physiology of the nervous system on the one hand, and psychology, or the science of mind, on the other. The concluding lectures of this course will be given in the Physicians' Hall, Queen-street, on Tuesday the 19th and Thursday the 21st June, at four p.m.

THE mortality of London is still greatly in excess of the average. The week before last the deaths were 1370 or 152 above the estimated number. Three deaths (two of them children) are referred to cholera, and three to hydrophobia.

THE LANCET'S BIBLIOGRAPHER.

THE inexcusable course adopted by the *Lancet* in regard to Dr. FOSTER'S book, which we exposed a few weeks since, is repeated in its last issue with even a more flagrant display of partiality and injustice to the author, and with an effrontery which seems to imply that the profession has no power of discriminating for itself. The reviewer has lashed Mr. ANNANDALE'S lately issued work on "Minor Surgery" with his severest scourge, printing parallel passages from it and Mr. CHRISTOPHER HEATH'S work on the same subject, and roundly taxing the author with gross and premeditated plagiarism. Here are the words of the indictment:—

"With the exception that the subjects treated of do not always follow in the same consecutive order, the plan of the work, and, in many instances, almost the very words, appear to us to have been borrowed from Mr. Heath, and this without the slightest acknowledgment from Mr. Annandale."

We have carefully read over the passages selected by the reviewer from the rival works to prove the charge of plagiarism, and we distinctly assert that not a single sentence quoted from Mr. ANNANDALE'S book bears any greater resemblance to that from Mr. HEATH'S than the essential similarity of the description warrants. It is as ridiculous as it is unfair to ground an accusation of plagiarism on such a similarity, because if such did not exist either work must be vague or incorrect. We quote for illustration one of the passages emphasized by the reviewer as conclusive against Mr. ANNANDALE:—

ANNANDALE.

"In performing the operation, the vein must be fixed below with the thumb, and an incision made into it in the direction of the fibres of the sterno-mastoid muscle. When sufficient blood has been extracted, a pad must be placed over the wound, and retained by means of a bandage or sticking-plaster."—p. 205.

HEATH.

"Bleeding from the jugular vein is rarely employed, but is performed in the following way:—The left thumb of the operator is to be placed on the vein, immediately above the clavicle, so as to obstruct the course of the blood. As soon as the vein is prominent, the lancet can be used, taking care that the incision is made parallel to the sterno-mastoid muscle, and thus somewhat across the vein. When sufficient blood has been drawn, a pad is to be placed on the orifice, and a bandage to be applied over it."—p. 86.

Paragraphs like this, and that "Mr. ANNANDALE'S book closely resembles Mr. HEATH'S in size, type, and number of pages," is considered by the *Lancet* sufficient ground for a charge of shameful fraud against a gentleman well known to be above such a fault. To us it appears that the reviewer who turns his pen from his legitimate work of honest criticism to the maintenance of a personal monopoly in any subject, and the promulgation of statements which he is utterly unable to prove, not only offends against professional propriety, but insults the discrimination of his readers.

MR. EWART has announced his intention of moving in Committee on the Capital Punishment Bill that the death penalty be abolished in the case of women. We have from time to time advocated warmly the total abolition of the death punishment, but we cannot see the semblance of a reason for confining its operation to the male sex. There are no murders more atrocious, more distinctly pre-

meditated, than those perpetrated by women (witness the crimes of Constance Kent and Charlotte Winsor), and if we could accept capital punishment at all it would be rather in such cases than in any other.

THE authorities of Guy's Hospital have appointed two Registrars for the purpose of superintending the work of the clinical clerks and hospital reporters on the medical and surgical sides respectively. Dr. Hilton Fagge is appointed for medicine, and Dr. George Eastes for surgery, at liberal salaries.

Provincial Intelligence.

BIRMINGHAM, JUNE 18, 1866.

FEW events of interest have occurred here since the last letter of your Correspondent. The Midland Medical Society has finished its session for 1865-66, after a series of very successful meetings. The papers read have been marked by more than ordinary ability and originality, and the attendance of members has been most satisfactory. Among the papers read at the last few meetings one by Mr. Furneaux Jordan, "On the Syphilitic Diseases of the long Bones," especially deserves mention. The author put forward some very original views as to the localization of these affections, and advanced the view that many of the diseased conditions of these bones now classed together under the term strumous are in reality manifestations of hereditary syphilis. The paper will, we believe, be shortly submitted to the profession in the pages of one of the medical journals.

Mr. Arthur Bracy placed before the Society at its last meeting a very interesting specimen of rupture of the aorta. The accident occurred in a young woman under thirty years of age, and had taken place suddenly without any discoverable cause. The rent had run obliquely round the vessel about one inch from its origin, and implicated only the internal and middle coats. The outer coat had ruptured afterwards from the pressure of the blood. Considerable patches of atheroma were visible on the inner coat.

The second Medical Society of this district, the Birmingham and Midland Counties Branch of the British Medical Association, held its annual meeting on Friday last. No business of special importance was transacted with the exception of a change in the hour of the ordinary meetings. The members have hitherto met at six o'clock in the evening, and the hour has been found very inconvenient for many of the country members, who have long distances to travel after the business of the Society has terminated. Several attempts have, therefore, been made to change the hour. The subject was fully discussed on Friday last, and on the representation of some of the country members, three o'clock in the afternoon was finally fixed upon as the hour of meeting for the next session. This change will, in our opinion, be found very beneficial, inasmuch as it will insure a much better attendance of the country members of the Society, and by thus making the meetings reunions of the majority of the medical practitioners of the midland counties, and not of a few only from the neighbourhood of Birmingham, render this branch of the British Medical Association one of the most flourishing in the kingdom. Dr. Carter of Leamington, succeeded Dr. James Russell as President, and Professor S. Berry was unanimously chosen President-Elect. After the

transaction of the ordinary business, the President (Dr. Carter) delivered an able and highly interesting address. Taking the treatment of rheumatic fever as an example of the changes which have of late years characterised the practice of medicine, he glanced at the various methods of medication which have from time to time found favour in the treatment of this malady. After analysing the theories on which these various methods have been based, he called attention to the statistics of the duration of the disease under various plans of treatment, published by Dr. Chambers, and to the cases treated on the expectant method in Guy's Hospital. In concluding, he expressed a strong faith that the hitherto slow progress of therapeutics would soon receive a fresh impetus, and that the scientific method of inquiry which had done so much for physiology and pathology would yield as rich fruits by giving precision to our views of the action of medicines.

A cordial vote of thanks to Dr. Carter for his address brought the business to a close, or rather allowed the members to adjourn to the annual dinner which so pleasantly winds up, year after year, the session of the branch.

The sanatorium scheme, of which the readers of THE MEDICAL PRESS AND CIRCULAR have from time to time heard, has proved very successful. Nearly £9000 have been obtained, and the committee are now deliberating upon the choice of a site, and collecting data from the different medical charities in Birmingham with reference to the number of beds likely to be required by each hospital. The strongest opinion prevails that no site within five miles of the town should be chosen, and in the opinion of many a building at a distance of ten miles would prove more suitable. In either case the sanatorium must be so placed as to be easy of access by one of the many lines of rail branching out of the midland metropolis.

The guardians of the poor for this borough have for some time been considering a plan for establishing a central dispensary. During the past month a sub-committee of the board has been collecting evidence on the subject, and some curious facts have been announced. Mr. Southall, in his evidence, for example, told the guardians that the in-patients at the workhouse infirmary cost about 1s. 11d. each case for drugs, while the calculation for the parish out-patients shows a cost of about 3d. per case. All the evidence hitherto submitted points in the strongest way to the necessity of some reform, and must convince even a board of guardians that the salaries of the parish medical officers—too small a remuneration for their heavy duties in attending the sick poor—must be a miserably inadequate recompense for medical attendance and the supply of drugs. By establishing a central dispensary, and by thus undertaking to provide the drugs, the guardians may make the necessary reform, and ensure a certain and adequate supply of medicines to that class of the community which is ever most exposed to disease, and placed in the least favourable conditions for contending against it.

THE BRITISH MEDICAL ASSOCIATION.

THE leading members of the profession in Dublin have, we understand, had under their consideration the propriety of inviting the British Medical Association to hold their Annual Meeting for 1867 in Dublin, and a very general feeling has been expressed in favour of such a course. The Association is eminently entitled to all the

honour which its Irish brethren can confer on it, and we trust that the invitation will be officially conveyed and promptly responded to by the Association. Its members in Ireland are not numerous, but, nevertheless, we are convinced that a hearty welcome will be accorded by the profession in Ireland.

[Since the above was in type, we have learned, on good authority, that the authorities of the University of Dublin, and also the President and Fellows of the King and Queen's College of Physicians have determined on inviting the British Medical Association to Dublin in 1867.—Ed. M. P. & C.]

MEDICAL PUFFERY.

THE *Londonderry Sentinel* of the 12th inst., among other excerpts, gives the following extract from the *Cork Examiner* :—

"SURGICAL OPERATIONS.—A series of surgical operations recently performed at the North Infirmary, by Dr. N. J. Hobart, has afforded that excellent practitioner an opportunity of introducing into Cork a new invention, by Dr. Richardson of London, which must prove of great value in totally obviating pain, and rendering the use of chloroform—an expedient generally resorted to with reluctance—unnecessary. The part to be operated upon, after being subjected for about two minutes to ether spray, is rendered completely insensible for the time. Dr. Hobart has now used it in a great variety of operations—such as the operation for carbuncles, opening abscesses of all kinds (including deep-seated abscesses of the breast), inserting setons, putting stitches in wounds, &c.; and in all these cases the patients, though themselves watching the performance of the operation, were completely insensible to pain. The apparatus has not yet been sufficiently perfected to enable limbs to be removed under its influence; but for all minor, yet intensely painful, operations it is a great boon, and is, moreover, unattended with any danger whatever."

A Subscriber asks, "is this in accordance with professional etiquette?" and we readily answer certainly not, *if inserted by Dr. N. J. Hobart*. There is no evidence, however, that such is the case; and we are slow to believe that so respectable a practitioner would do anything of the kind. The *Cork Examiner* is well affected to the profession, and in all probability would not become subservient to professional puffery.

It seems to be fashionable to put accounts of surgical operations in the daily papers. The following extract shows something of this kind, and as we have above alluded to Dr. N. J. Hobart, a Cork practitioner, we refer to Dr. Kavanagh, merely to say we very much doubt that gentleman being in any way a party to this kind of puffery. Each of these gentlemen may well say, "save me from my friends":—

"ETHER SPRAY.—The medical men of Limerick and Cork are introducing, with the most merciful effect to suffering humanity, the singularly safe and simple agency of the medical lenitive above named, of the qualities of which in relation to chloroform, and the effects in surgical operations, a statement appeared recently in these columns. The invention is due to Dr. Richardson of London, and from all that appears, mankind will have reason to bless the man by whom this assuasive of agony has been placed in the hands of the life-saving profession to which he belongs. It was applied, we find, on Monday last, at Barrington's Hospital by Dr. Kavanagh, in the presence of the other surgeons of the institution, for the removal of a tumour from the armpit of a young woman, who had been suffering from it for the last two years. It was larger than a hen-egg, and though nine other tumours of smaller size were found under the large one, necessarily causing some delay in their extirpation, the cutting and other manipulation were entirely unfeared by the patient. This simple invention will be a boon and a blessing to the afflicted. By its use some of the most

painful operations of surgery can be performed with complete immunity from suffering and unattended by the slightest risk. The benumbing effects of the agent are produced by its rapidly reducing the temperature of the part it is applied to below the freezing point. Ether being highly volatile, when brought into contact with a warm surface, it becomes suddenly changed from fluid to a state of vapour. The change is brought about by the chemical law of denser bodies when passing into a rarer state, absorbing from surrounding objects, heat, which is rendered latent. In this case the heat is absorbed from the part to be operated upon; or, in other words, the part is made perfectly cold and benumbed to insensibility."

Parliamentary Intelligence.

HOUSE OF LORDS.—JUNE 18TH.

MEDICAL ASSISTANCE AT POLICE STATIONS.

THE MARQUIS TOWNSHEND asked whether any instructions had recently been given to the police relative to the treatment of persons in a state of insensibility taken to police stations.

LORD STANLEY of ALDERLY was understood to say that the police had been instructed on such occasions to send for medical assistance.

HOUSE OF COMMONS.—JUNE 14TH.

POOR-LAW BOARD REPORTS.

Colonel HOGG asked the President of the Poor-law Board whether he would lay the reports of Mr. Farnall and Dr. Smith on the state of the metropolitan workhouses when complete upon the table of the House.

LORD ENFIELD replied that the report of Mr. Farnall was complete, and as soon as that of Dr. Smith was ready both would be laid on the table of the House.

MEDICAL OFFICERS OF THE ARMY AND NAVY.

In reply to a question from Colonel North, Mr. CHILDERS said that in July last the College of Physicians wrote to the War Office, complaining that the status of the army surgeons was unsatisfactory, and to the Admiralty, stating that the condition of the navy surgeons was not on a par with the army surgeons. In consequence of these representations the two departments had appointed a committee to inquire into the rank, pay, and position of the surgeons. The Treasury were not yet aware of the result of the inquiry, but when they should be placed in possession of the views of the two departments they would be able to deal with both the army and navy surgeons. The question was an important one, and involved the expenditure of a considerable amount of public money.

REGISTRATION OF DOGS.

MR. BUTLER asked the Secretary of State for the Home Department whether it was the intention of her Majesty's Government to introduce during the present session any measure for the registration of dogs, with a view to the prevention of hydrophobia and of other injuries to person and property, for which the owners of dogs are not now practically responsible.

SIR G. GREY replied that a measure would shortly be introduced to abate the nuisance complained of (hear).

PUBLIC HEALTH BILL.

On the motion of Mr. BRUCE, the Select Committee on the Public Health Bill was nominated.

JUNE 19TH.

THE RINDERPEST.

MR. NORWOOD asked the Vice-President of the Committee of Council on Education whether he was aware that the provinces of Groningen and Friesland, in Holland, had been and still were free from the rinderpest, and that stringent precautions were taken by the authorities there to prevent its introduction; and whether the attention of the committee was directed to the advisability of an immediate relaxation of the prohibition of the import of cattle from Groningen and Friesland.

MR. BRUCE said he believed it was true that the cattle in those two provinces had been and still were free from the rinderpest; and precautions had been taken by the authorities there to prevent its introduction. The Government had recently directed inquiries to be made with a view to see whether the importation of cattle could be permitted without any danger of contact with diseased animals.

METROPOLITAN WORKHOUSES.

MR. DAVENPORT BROMLEY put the question of which he had given notice on this subject; but as it was afterwards discovered that the President of the Poor-law Board was not in his place, the matter dropped without any answer being given.

GRIFFIN TESTIMONIAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly insert this circular which has been posted to every Poor-law Medical Officer in England and Wales, and also every Subscriber to the Griffin Testimonial Fund.—I am, Sir, yours obediently, ROBERT FOWLER.

145, Bishopsgate-street, Without, June 20, 1866.

"DEAR SIR,—I beg to inform you that the presentation of the above will take place at a public meeting, to be held at the Freemasons' Tavern, Great Queen-street, on Thursday, July 5th proximo, at three p.m. in the day.

"If you have not forwarded me your subscription to the fund, I would respectfully ask that you *at once* do so.

"Let each and all thus show some slight appreciation of, and some gratitude for, those untiring energies which, during the last ten or eleven years, our champion has bestowed on the cause of Poor-law Medical Reform. I enclose a copy of Mr. Griffin's last letter to the journals, to show you how continually watchful he is of our interests.

"If also you have not sent me your Carte de Visite (as very many of the subscribers have done), I hope to receive it in time for the Photographic Album of Mr. Griffin's friends and admirers, with which it is decided additionally to present him. Let your Carte de Visite have your designation, profession, title, and (if a Poor-law Medical Officer) the name of your union plainly written on the back.

"Should it be your intention to attend the meeting (*no banquet*), it would be a great convenience if you would inform me thereof on or before the 30th instant.

"The testimonial is now on view at the manufacturers, Messrs. Mappin and Webb, 71 and 72, Cornhill.—Yours faithfully, "ROBERT FOWLER, M.D., Treas. and Hon. Sec.

"145, Bishopsgate-street, Without, June 20, 1866."

COURT OF QUEEN'S BENCH.—WESTMINSTER, JUNE 16.

(Sittings at Nisi Prius, before the LORD CHIEF JUSTICE and a Special Jury.)

PERIONOWSKI v. FREEMAN AND ANOTHER.

THE plaintiff, who is by birth a Pole, and by trade a tailor, professed to be unable to understand English enough to be examined in it, although he gave evidence of conversations and statements by the defendants. In May last year he had suffered from a disease, for which he had become a patient in the hospital, and which required a warm hip-bath. According to his account, the defendants, the surgeons, not only ordered it, but were present and personally directed it, and he was actually forced into and kept in a steam hip-bath, in which the water was so hot that it severely scalded him. The defence turned upon the point that the defendants, the surgeons, having ordered that the patient should have a hot hip-bath, went on to attend other patients in the same ward, and were not present when he was put into it; and when they came back, a quarter of an hour afterwards, found him upon the bed. There was no doubt that at that time he had been somewhat scalded, although it was said that the extent of the injury was greatly exaggerated. But whatever it might have been, the defence, in a word, was, that it was not their fault, and that it arose from the negligence of the nurses. And, indeed, the only witness produced by the plaintiff (besides himself) who was personally present on the occasion, could not, when he was pressed in cross-examination, positively state that the surgeons had

returned before the man was out of his bath; and the only medical witness called for the plaintiff, who was asked a question as to the duty of surgeons on such occasions, stated that it was no part of a surgeon's duty to be present, when a hot bath was administered, to test its heat, but that this was a matter ordinarily left in the hands of nurses. The case for the plaintiff, however, as sworn to by himself and his witness, was that he screamed out and struggled with the nurses when he found the water too hot, and that they held him down, and that the medical men who were in the ward must have heard his screams. The defence, in substance was, that it was practically impossible that surgeons should personally attend to such matters, their patients were far too numerous, and their duties too onerous to admit of their discharging the duties of nurses in addition to their own. The defendants were called in support of the defence, and stated positively that they were not present when the man was put into his bath, but had gone on to attend other patients in the same ward, and that they heard no sound of screaming or struggling, nor heard any complaint from the man when they came back to him, and in this they were confirmed by two medical students who were with them. Their directions, they said, were that the water should be as hot as the patient could comfortably bear, and it was not necessary that it should be very hot. The man was not, in fact, to sit in the hot water, but over it—for the sake of the hot vapour. They both positively swore that the man made no complaint of scalding, and that there were no appearances of it, at the time; nor did they see or hear anything of the scuffling or screaming which the plaintiff had described in his evidence. However, a few days afterwards—hearing something about scalding—one of them examined him and found he was scalded, but up to that time he had made no complaint. They stated that there were 200 surgical and 150 medical patients in the hospital, and there were four surgeons, each of whom had about 50 patients to attend to. There was a record kept of the cases, in a book at the hospital. There were two nurses engaged in this case, who put the man in the hip-bath. The surgeons had no control over the nurses as to appointment or dismissal, which rested with the board. When the complaint was made they desired that it might be sent to the board to be inquired into. That course, however was not taken, but this action was brought. Besides the defendants themselves some very eminent medical gentlemen were examined on their behalf. Mr. Paget, one of the senior surgeons of St. Bartholomew's Hospital (and who had examined the man), and Mr. Curling, one of the senior surgeons of the London Hospital, stated that it was no part of the duties of the surgeons in such cases to be present on such occasions, or to see to the temperature of the water, which, they said, was part of the "familiar knowledge" of the nurses. The doctors gave their directions that patients were to have hot baths, and left it to the nurses to see to the baths. And this, they said, was the usual hospital practice. In answer to the Lord Chief Justice, Mr. Paget said that when hospital surgeons had ordered a patient a hot bath there was nothing at all inconsistent with the proper discharge of their duties that they should go on to attend to other patients; but that, on the contrary, it was the usual course of hospital practice. In this Mr. Curling entirely concurred, adding that it was practically impossible, from the number of patients, that they should take any other course. Mr. Curling also said, as Mr. Paget had said, that a surgeon no more knew what was the fit temperature of hot water for a bath than a nurse, who was necessarily quite familiar with it. The nurses were not called on either side. This being the evidence,

The Lord Chief Justice observed that as this was proved to be the usual hospital practice, and as a person who became a patient in an hospital could expect no more than the usual and ordinary degree of care and attention, this action would not be maintainable merely for the negligence of the nurses. And the only question would be whether the defendants were liable, by reason of their personal presence on the occasion, which they denied. The sole point, therefore, was whether they were personally present when the man was put into the bath.

Mr. Huddleston, the counsel for the plaintiff, acquiesced in this view, and contended that the defendants were near enough to have known of and prevented the mischief.

Mr. Coleridge, for the defence, insisted that the negligence was that of the nurses, and that they or the hospital authorities who employed them were properly liable, not the

unpaid hospital surgeons, who had no power to dismiss them. The nurses, he urged, were the parties really liable, and for that reason he had not thought proper to call them as witnesses.

Mr. Huddleston, in reply, urged that the nurses ought to have been called as witnesses for the defence; and he suggested that the defendants must or might have heard the screams and scuffling with the nurses to which the plaintiff and his witness swore, and that therefore they were liable for not interfering to prevent the injury.

The Lord Chief Justice, in summing up the case to the jury, observed that our great hospitals, supported, as they were, entirely by alms and voluntary subscriptions, could not be supported if they had to engage a staff of medical men sufficient to attend to all the minor incidents or details of medical or surgical operations which might be ordered, such as baths. It was indispensable that such matters should be left to nurses, who were necessarily familiar with them; and it had been satisfactorily proved by the testimony of some of the most eminent medical attendants of our hospitals that such was the ordinary and usual course of hospital practice. That being so, the question was whether the defendants had been present when the man was put into the bath or were near enough to observe what had occurred, which it was probable had been greatly exaggerated. It was well known that medical men were always anxious that no unnecessary pain should be inflicted upon their patients; and it was incredible that they should have allowed the man to be treated in their presence as had been described by him. This would be to impute to them a gross and senseless inhumanity which passed all the bounds and limits of probability. The defendants would not be liable for the negligence of the nurses, unless near enough to be aware of it and to prevent it. It was not because the plaintiff might have sustained some amount of injury that therefore a verdict was to be given against gentlemen who were not really responsible for it. And the statements of the plaintiff must be regarded with some degree of distrust, seeing that, although he professed to be unable to understand English, he had spoken to conversations in that language. No doubt persons who went as patients into hospitals were not to be treated with negligence; but, on the other hand, medical gentlemen who gave their services gratuitously were not to be made liable for negligence for which they were not responsible.

The jury at first appeared to disagree, and prepared to retire to consider their verdict; but, in the result, agreed to a verdict for the defendants, adding that they thought the plaintiff had been ill-used.

Our Weekly Retrospect of the Medical Journals.

JUNE 22ND.

THE various journals have leaders on the subject of the trial in the Court of Queen's Bench, in which the Pole Perionowski was plaintiff, and Surgeons Holmes and Freeman, of St. George's Hospital, were defendants. The plaintiff while in hospital had been scalded by the negligence of the nurses of the hospital, and the suit should have been instituted against the hospital authorities instead of the surgeons. The whole case is very trivial, and one evidently got up for obtaining money, in which, however, the expectation was not realized, as the jury, although admitting that the plaintiff had been injured, yet found for the defendants. The hospital board, we understand, paid all the expenses of the defence. This accident has opened up the question debated some time ago in the board-room of this very institution, as to the advisability of placing the patients under the care of a religious sisterhood, which would take the whole responsibility of the nursing.

The cattle plague returns are rapidly decreasing. The *Lancet* hopes that Drs. Markham and Dewar may be permitted to perform some experiments of a scientific nature; the former has already suggested the transfusion of whipped blood, the latter proposed sulphurous acid gas for the destruction of the poison.

In and about London the dog nuisance has become

unbearable. Many dog bites have been reported, and some cases of hydrophobia.

The Rotherhithe inquiry does not exhibit the poor-law guardians, who tolerated such a system of neglect and inhumanity, to any advantage:—"The woman Brutton was a sort of fiend, who, in the intervals of opium-eating, indulged in the most savage brutality: the dragging of patients in the last stage of disease to the closets, and their dying on the floor (as was proved in two cases within a short space of time), were examples of special neglect and unusual hardship; but it is a characteristic fact that, although these things were proved beyond doubt or cavil by a number of independent witnesses, whose separate evidence was in every instance confirmed and corroborated, the guardians maintained throughout a tone of injured innocence, and the chaplain was called to give them a good character. The doctor, it appears, is in receipt of £20 per annum as a net salary for the performance of most onerous daily duties, and is subject to annual re-election. He is a gentleman and a man of intelligence."

Our contemporary suggests the use of an universal system of short-hand among medical and scientific men; if such were adopted the printers would soon learn to set up type from it as well as from the most perfect caligraphy.

The baronetcy of Sir Thomas Watson has been gazetted, there is but one feeling of general satisfaction evidenced by every branch and individual of the profession.

The Austrian War Office do not intend to accept the services of foreign medical gentlemen until all who have studied in Austrian or German universities have been absorbed.

Dr. Lankester writes a long letter, explaining the difficult position in which he is placed, and the hard card he has to play in his dealings with medical men; he also shows that the large salary which he is supposed to enjoy is very much reduced by expenses.

The woman Forester has been acquitted; it may be recollected that she was indicted for procuring abortion in a married woman, who died from the treatment she received. Dr. Brown's evidence was contradictory as to the exact words used by the dying woman. This was the means by which the prisoner escaped.

Dr. Rogers writes of the good effect of quinine in the hectic fever of phthisis.

Professor Hancock reviews in his lecture the various operations of a conservative nature which have been undertaken from time to time for the removal of portions of the foot.

Dr. Mandsley describes cases of a particular form of insanity, which might be called impulsive, the person all the while being conscious of the act and its consequences, but unable to prevent it.

A case of necrosis of the lower jaw is recorded from Bartholomew's, in which the disease was traceable to the application of the oil of tobacco to a hollow tooth.

From the *Medical Times and Gazette* we learn that Dr. Viallet urges the necessity of establishing a School of Midwifery in each of the French departments.

Attention is drawn to the Fellowship of the College of Physicians, about which there is evidently some dissatisfaction, some of the recipients of that honour not being deemed sufficiently worthy of it.

Dr. Richardson's views as to the curability of the rinderpest, and its treatment by the injection of artificial chyle, have been submitted to the Privy Council of Ireland.

The account of the method of treatment of fractures in the London hospitals is resumed.

The *British Medical Journal* announces that Dr. Dyster, a warm admirer of the late Dr. Baly, being anxious to perpetuate his name, has generously placed £400 at the disposition of the College of Physicians, for the purpose of providing for the presentation of a medal occasionally for the best essay on physiological subjects.

The Cæsarean section has been performed in Liverpool by Dr. Grimsdale for distortion of the pelvis. The mother was doing well forty-eight hours after the operation.

ANNUAL BANQUET OF THE LICENTIATES IN DENTISTRY OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THIS festival was celebrated on Tuesday, the 5th of June, 1866, at the Albion Tavern, Aldersgate-street, City,

F. C. SKEY, Esq., in the chair.

On the removal of the cloth, and after the usual loyal and patriotic toasts had been honoured,

The CHAIRMAN proposed the toast of the evening, "The Diploma of Licentiates in Dental Surgery." After taking a retrospection of the dental profession, he said that the reason there were not so many extractions now as formerly was owing to the pathological knowledge that the licentiates in dentistry had imbibed; this it was that had saved thousands of teeth as it had saved thousands of limbs in the hospitals. He begged to ask the gentlemen present to join with him in drinking the toast.

The toast was drunk with great cordiality.

Mr. UNDERWOOD, in acknowledging the toast, said he considered, now that the College had granted a diploma for dental surgery, it remained for the dentists to show whether they were worthy of that rank, for it was a degree that they might justly be proud of and a passport for he who had obtained it, to show that he was competent to practise his profession. He (Mr. Underwood) trusted that the licentiates would never disgrace their place in the College of Surgeons, but carry her good name before her, so that she should never regret having entered the names of the dental licentiates.

Dr. ROBERTS of Edinburgh proposed "The Health of the Examiners of Dental Surgery."

Mr. HARRISON, in thanking the gentlemen for the manner in which they had drunk that toast, hoped that the examiners would be worthy of the honour the College had conferred upon them.

The toast of "The College of Surgeons" was proposed by Mr. Rymen.

Mr. LUKE, in reply to the toast, said that he considered the College of Surgeons had conferred some benefit on dentistry, and that dentistry had conferred some benefit on the College of Surgeons.

Mr. CARTWRIGHT, in proposing the toast of the "Medical and Scientific Societies," coupling with them the "Odontological Society," said he considered the latter society had been the means of bringing men together to read and discuss on papers that would otherwise never have known each other.

Mr. CATTLIN, President of the Odontological Society, in acknowledging the toast, was proud of his present position as president. The Odontological Society had been the main instrument in forming the Dental Hospital; but not only had it done this, but it had also raised members of the dental profession to a higher position. That the Odontological Society had done good, and was at present rising, no one could deny, and in the name of that society he begged to return thanks for the toast.

Mr. MUMMERY proposed the health of the licentiates in dental surgery present from the provinces, which was acknowledged by Mr. Hepburn of Edinburgh.

The health of the Chairman, proposed by Mr. James Parkinson, was acknowledged in a very humorous speech by Mr. Skey, who, in conclusion, proposed the health of the Stewards, coupled with the name of Mr. Alfred Hill.

Mr. ALFRED HILL returned thanks on the part of the Stewards and himself, and thought that in these times it was necessary to meet together after our daily toil, and he believed that in doing so they went forth with fresh courage. He much regretted the absence of Mr. Arnold Rogers, which was caused through sickness. In conclusion, he assured them that whatever trouble they as Stewards had taken was fully remunerative by the way in which their health had been drunk.

During the evening several glees and solos were sung under the direction of Mr. Baxter, assisted by Mr. W. Coates, Mr. F. Walker, and Mr. Winer.

SIR THOMAS WATSON, M.D., BART.

THE news of the well-merited, though somewhat tardy, honour conferred on the respected President of the Royal College of Physicians of London, will be received throughout the profession with unanimous satisfaction. It is almost superfluous to mention the numerous claims which Sir Thomas presents for this dignity, that of the Presidency of the College being only one out of many. As a scholar and a gentleman, an able writer, an elegant and dignified speaker, and an accomplished practitioner, he has long held the foremost rank among the physicians of the metropolis; and we only echo the sentiment of thousands when we wish him long life and health in the enjoyment of the honour which has fallen to his lot.

THE METROPOLITAN POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

At a preliminary meeting of Metropolitan Poor-law Medical Officers, held at the house of Mr. Godrich, Medical Officer of St. George's, on the 20th inst.—Dr. Rogers of the Strand Union, in the chair—it was unanimously resolved:

"1. That an Association be formed, to be called 'The Metropolitan Poor-law Medical Officers' Association.'

"2. That the annexed form of address be printed and sent to every parochial medical officer within the metropolitan district.

"3. That the following gentlemen be appointed officers of the Association *pro tem.*:—Dr. Rogers (Strand Union), President; F. Godrich, Esq. (St. George's, Hanover-square), Treasurer; Dr. Dudfield (St. Margaret's and St. John's, Westminster), Honorary Secretary."

DEAR SIR,—An Association of Metropolitan Union and District Poor-law Medical Officers has been formed, with the object of mutual assistance in any difficulties arising out of our duties; and also for the purpose of urging upon our respective local boards, the Poor-law Board, and the public, that amendment of our position as public servants as our status as members of a learned and scientific profession demands.

The present moment is opportune for the formation of such an Association, inasmuch as recent revelations have clearly demonstrated the absolute necessity of some change in the system of metropolitan poor-law medical relief, and the public are prepared to urge some alteration on the Legislature.

Under these circumstances, for us to remain quiescent is to allow those who would aid us to form the conclusion that we are indifferent to the just claims of the sick poor, and careless of our position as State servants.

We consider that a small annual subscription will be sufficient to cover our working expenses.

Should you feel disposed to join us, you will kindly signify the same to one of the undersigned at your earliest convenience.—We are, dear Sir, yours faithfully,

JOSEPH ROGERS, *President (pro tem.)*

FRANCIS GODRICH, *Treasurer.*

Grove House, West Bromton.

T. ORNE DUDFIELD, M.D., *Hon. Sec. (pro tem.)*,
8, Upper Phillimore-place, Kensington.

P.S.—Another meeting will be shortly held, of which due notice will be given.

WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON.—The following officers for the session 1866-7 were elected at the last annual meeting:—President: Dr. Fuller. Vice-presidents: Mr. Prescott Hewett, Dr. Marcet, Mr. T. Dickinson, and Dr. Anstie. Council: Dr. Way, Mr. Vasey, Dr. D. Davies, Mr. Traer, Mr. Knight, Dr. Daniell, Dr. Blandford, Mr. T. Holmes, Mr. J. R. Lave, Dr. Morell Mackenzie, Mr. Naylor, and Dr. Fyfe. Treasurer: Dr. Baines. Hon. Secretaries: Mr. Milner and Mr. C. Hunter. Hon. Librarian: Dr. Godwin. Auditors: Mr. T. Taylor and Mr. Hall.

Medical News.

ROYAL COLLEGE PHYSICIANS OF LONDON.—At a general meeting of the Fellows held on June 15th, the following gentlemen, having undergone the necessary examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

Hallett, Thos. Geo. Palmer, Queen's-crescent, Haverstock-hill.
Humphreys, Frederick Will, Trinity-square.
May, Henry, Birmingham.
Nankivell, Arthur Wolcot, Torquay.
Oppert, Francis, M.D. Berlin, Great Russell-street.
Parsons, Daniel Walter, Liverpool.
Power, Richard Eaton, Portsea.
Webster, Thomas, Redland, near Bristol.

At the same meeting, the following were reported by the Examiners to have passed their Primary Examination:—

Smith, Frederick Walter, St. Thomas's Hospital.
Toulmin, William, Guy's Hospital.

QUEEN'S UNIVERSITY IN IRELAND.—At a meeting of the Senate of the above University, held on Wednesday, the 20th inst., in the Council Chamber, Dublin Castle, the following Degrees in Medicine and Surgery were conferred by the Right Hon. the Lord Chancellor of Ireland, Vice-Chancellor of the University:—

Doctors in Medicine.

Thomas St. John Clerke, of Queen's College, Cork; William Collins, of Queen's College, Cork; George John Gibson, of Queen's College, Cork; John Macaulay, of Queen's College, Belfast; Newnham Edward Maher, of Queen's College, Galway; Edwin Field Nelson, of Queen's College, Belfast; Samuel Parke, of Queen's College, Belfast; James Edward Saunderson, B.A., of Queen's College, Galway; William Sharpe, of Queen's College, Galway and Belfast; George V. Wood, of Queen's College, Cork, Belfast, and Galway; Alexander Young, of Queen's College, Belfast.

Masters in Surgery.

William Collins, of Queen's College, Cork; Barry Delaney, M.D., of Queen's College, Cork; Alexander Filson, B.A., M.D., of Queen's College, Belfast; George John Gibson, of Queen's College, Cork.

APOTHECARIES' HALL OF LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on June 14th:—

Harrison, Jonathan Atkinson, Wirksworth, Derbyshire.
Harvey, Thomas, Waterloo-road.
Sargent, James Forbes, Bentinck-terrace, Regent's-park.
Schott, Georg Friedrich Julius, Frankfurt-on-the-Maine.
Spearman, George, Plymouth.
Stevens, George, Jesse Barnabas, Strood, Kent.
Thurston, William French, South-bank, Notting-hill.
Wathen, John Handcocke, Fishguard, Pembrokeshire.

The following gentlemen also on the same day passed their first examination:—

Codrington, John Frederic, Guy's Hospital.
Fiddian, Alex. Paull, King's College Hospital.
Stothard, William Jepson, Guy's Hospital.

The following gentlemen passed their examination on May 31st:—

Bond, Thomas, 6, Carey-street, London.
Cullingworth, Charles James, Bawtry, Yorkshire.
Greene, James Shirwen, St. George's, near Wellington.
Lloyd, Ridgway Robert S. C. C., Doncaster.
Noel, Vincent Edmund, Westbury-terrace, Plymouth.
Owen, Richard Walter, Withers, Shrewsbury.
Smith, Frederick, Westminster.
Smith, Joseph William, Weaverham, Cheshire.
Upton, Herbert Chrippes, Petworth-park, Sussex.

As an Assistant:—

Sympson, William F. G. Wilson, Fenny Stratford, Bucks.

The following gentleman also on the same day passed his first examination:—

Worthing, Charles James, Guy's Hospital.

OPHTHALMIA is said to be raging among the women and children of the troops in Meerut.

PROFESSOR W. BYRD POWELL, an eminent American physician and phrenologist, lately dead, bequeathed his head to one of his pupils, a Mrs. Kinsey. The executor of the deceased employed Dr. Curtis of Cincinnati, to take off the head, and it is now in the possession of the fortunate legatee.

A COTTAGE HOSPITAL is to be immediately opened at Warminster, a house and garden having been promised by the Marquis of Bath at a nominal rent of 10s. a year, for the purpose. The medical gentlemen of the town have intimated their willingness to give their services gratuitously.

PROFESSOR FARADAY lately received at his residence (being too unwell to attend a public meeting), the Albert gold medal of the Society of Arts, which has been awarded to him for his discoveries in electricity, magnetism, and chemistry.

A Parliamentary return gives the number of members on the books of the General Council of the Universities of Scotland, whether by degree or by attendance on classes during the requisite number of sessions. Edinburgh is returned as having 2400 names on its register; Glasgow, 1165; Aberdeen, 898; St. Andrews, 369.

THE ROYAL IRISH ACADEMY.—The following have been elected members of the Royal Irish Academy:—J. A. Baker, F.R.C.S.I.; E. H. Bennett, M.D.; F. R. Cruise, M.D.

CHARING-CROSS HOSPITAL.—At a large meeting of the governors of this institution on Monday week Dr. Julius Pollock, Physician to the Foundling Hospital, was elected one of the physicians to the hospital. Dr. Pollock is a son of the venerable Lord Chief Baron.

DR. JOHN YOUNG, F.R.S.E., F.G.S., has been appointed by Sir George Grey to fill the chair of Natural History in the University of Glasgow, vacant by the death of Professor Rogers.

THE cholera has established itself in Stettin, and in a tolerably severe form. In the nine days from June 2 to June 11, there had been 190 cases, of which 104 had been fatal. At Arnswalde, a town with a population of only 7000, there have been sixty-three deaths in sixty-three days. A few cases have also occurred in Berlin, and several houses are being fitted up as hospitals, in case they should become necessary.

THE Cattle Plague returns have reported 987 attacks in Great Britain as occurring during the week ended June 9.

THE Prussian Government have applied to the Deaconness Institution at Kaiserworth to send them sixteen deaconesses to superintend the nursing of the army.

At the annual commemoration of Founders and Benefactors of the University of Oxford, the degree of D.C.L. was conferred upon Sir James Young Simpson, Bart., the distinguished Professor of Midwifery and Medicine in the University of Edinburgh.

THE EPILEPTIC HOSPITAL.—The Amateur Morning Concert for the benefit of the London Infirmary for Epilepsy and Paralysis, Charles-street, Portman-square, came off on Tuesday, the 12th inst., at Willis's Rooms, which were crowded by a large and fashionable audience. Amongst the performers were Lady John Manners, Mrs. Althaus, Mrs. Sheffield Neave, the Misses Alderson, the Misses Baillie, Miss Connor, Mr. Coleridge, and many other distinguished vocalists and instrumentalists. About £180 was realized on the occasion.

BOOKS RECEIVED.

Note-Book of Materia Medica, Pharmacology, and Therapeutics. By E. Scoresby-Jackson, M.D., F.R.S.E., &c. &c. Edinburgh: Maclachlan and Stewart. Pp. 632.

These Lozenges have a remarkable effect in allaying Cough and Irritation of the Throat and Chest. Prepared only by T. and H. SMITH and CO., 21, Duke-street, Edinburgh, and 69, Coleman-street, London; and to be had of any Chemist and Druggist; in Boxes at 1s. 1½d. and 2s. 9d. each.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Notice to Medical Students.

PRELIMINARY EXAMINATIONS IN ARTS.

THE FOURTH PRELIMINARY EXAMINATION IN ARTS for the Session 1865-66, will be held at the College on Saturday, the 14th July, at 12 o'clock.

Students intending to present themselves for Examination can obtain information as to the Subjects of Examination, at the College, in Kildare-street.

LOMBE ATTHILL, M.D.,

Fellow and Registrar.

County and City of Cork Medical Protective Association.

At a special meeting of the Committee, called by requisition and held at the Royal Cork Institution, June 18th, 1866, it was proposed by Dr. O'Connor, seconded by Dr. Beamish, and carried unanimously:—

Resolved—"That, while we consider that members of our profession might confer great advantage on the public medical institutions by taking part in their general administration, we are, nevertheless, of opinion, that any interference whatever of a purely professional nature, by such members, with the duties of the responsible medical officers of these institutions, cannot fail to be productive of evil to the patients, and to bring discredit on the profession."

JOSHUA R. HARVEY, M.D., Chairman.
 CHARLES ARMSTRONG, M.D., Hon. Sec.

LISNASKEA UNION.

LISNASKEA DISPENSARY DISTRICT.

The Committee of Management of the

above Dispensary District will, at their Meeting, to be held on Saturday, the 14th day of July next, proceed to appoint a properly-qualified Midwife, at a salary of £20 per annum, with liberty of private practice under the sanction of the Committee.

Applications, with testimonials, to be forwarded on or before the 14th day of July next, to BLANEY LESLIE, Esq., Honorary Secretary, Nutfield, Lisnaskea. Applicants to be in attendance at the Workhouse at the hour of Twelve o'clock on the above date.

BLANEY LESLIE, Esq., Hon. Sec.

Dispensary Room, 23rd June, 1866.

CONTENTS.

VOLUME I. SECOND SERIES. JANUARY TO JUNE, 1866.

- Abscess, chronic, treatment of by iodine injections, 300, 417; by drainage, 592; puerperal fœtid pulmonary, 630
- Acupressure, application of, in amputation of thigh, 272
- Adipose cellular tissue, changes in, 342
- Advertisements, quack, 182
- Age, retention of mental vigour in old, 467
- Alcohol, detection of, 485
- Algeria, hospitals for natives in, 318, 382
- American war, the late history of, 307, 382, 616
- Ammonia, excretion of, by the lungs, 514
- Aneurism, dissecting, 56; popliteal, 100; primitive false, of femoral artery, 176; thoracic, 403, 448, 565
- Anæsthetic, the new, 19; remarks on, 218, 234, 293, 465; in dental operations, 247; letter on, 321; Mr. Porter on, 395; Dr. MacCorinac on, 445; Dr. Drysdale on, 506
- Anthrax, treatment of, by pressure, 484
- Aphonia, treatment of functional, by galvanism, 23, 29
- Apparatus, the new anæsthetic, 203; an, for fire damp, 342
- Arachnitis, on cerebro-spinal, 540, 561
- Army medical department, 133; medical examination, 353; and navy medical service, 386, 552
- Ascites, case of, 333
- Ashe, Dr. selection from French medical literature—on the treatment of cholera by M. Foiesac, 30
- Assistant, manslaughter by an, 133; charged with, 263
- Association, Cork Protective, annual meeting of, 392; Sanitary, of London, 312; Medical, of Ireland, 615; Metropolitan Counties Branch of British, 641
- Ataxy, progressive locomotor, 252, 538
